<tr>
<td>Notify surgeon.</td>
</tr>
</tbody>
</table>
- Notify Surgeon, stop nitrous oxide and volatile agents. Increase $O_2$ to 100%.

- Stop air entrainment: Find air entry point, stop source, and limit further entry.
  - Ask surgeon to:
    - Flood wound with irrigation/soaked saline dressing
    - Turn off all pressurized gas sources, e.g. laparoscope, endoscope
    - Place bone wax or cement on exposed bone edges
  - Check for open venous lines or air in IV tubing
  - Lower surgical site below level of heart (if possible)
  - Perform Valsalva on patient using hand ventilation

- Consider:
  - Compress jugular veins intermittently if head or cranial case
  - Aspirate from central venous catheter

- Hemodynamic support if hypotensive:
  - Give epinephrine 1-10 MICROgrams/kg, followed by infusion of epinephrine 0.02-1 MICROgrams/kg/min or norepinephrine 0.05-2 MICROgrams/kg/min
  - Chest compressions: 100/min to force air through lock, even if not in cardiac arrest
  - If available, call for transesophageal echocardiography

- If cardiac arrest, see card: asystole/PEA or VF/VT
Anaphylaxis

- Increase $O_2$ to 100%
- Remove suspected trigger(s)
  - If latex is suspected, thoroughly wash area
- Ensure adequate ventilation/oxygenation
- If HYPOtensive, turn off anesthetic agents

**Common causative agents:**
- Neuromuscular blockers
- Latex
- Chlorhexidine
- IV colloids
- Antibiotics

### Purpose | Treatments | Dosage and Administration
---|---|---
To restore intravascular volume | NS or LR | 10-30 mL/kg IV/IO, **rapidly**
To restore BP and ↓ mediator release | Epinephrine | 1-10 MICROgrams/kg IV/IO, as needed, may need infusion 0.02-0.2 MICROgrams/kg/min
For continued ↓ BP after epinephrine given | Vasopressin | 10 MICROunits/kg IV
To ↓ bronchoconstriction | Albuterol (Beta-agonists) | 4-10 puffs as needed
To ↓ mediator release | MethylPREDNISolone | 2 mg/kg IV/IO MAX 100 mg
To ↓ histamine-mediated effects | DiphenhydrAMINE | 1 mg/kg IV/IO MAX 50 mg
To ↓ effects of histamine | Famotidine or Ranitidine | 0.25 mg/kg IV 1 mg/kg IV

- For laboratory confirmation, if needed, send mast cell tryptase level within 2 hours of event
## Anterior Mediastinal Mass

- Increase O₂ to 100%

### Intra-operative Treatments

<table>
<thead>
<tr>
<th>Airway collapse</th>
<th>Cardiovascular collapse</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Increase FiO₂</td>
<td>- Give fluid bolus</td>
</tr>
<tr>

</tr>
</tbody>
</table>

If hypotensive, pulseless, or poor perfusion, start chest compressions
- Give epinephrine 10 MICROgrams/kg IV
- Call for transcutaneous pacer (see inset)
  - Start pacing, when available

If NOT hypotensive or pulseless:

<table>
<thead>
<tr>
<th>Etiology</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypoxia (most common)</td>
<td>▪ Give 100% O₂</td>

<td>▪ See ‘Hypoxia’ card</td>
</tr>
<tr>
<td>Vagal</td>
<td>▪ Atropine 0.01-0.02 mg/kg IV</td>
</tr>
<tr>
<td>Surgical Stimulation</td>
<td>▪ Stop stimulation</td>
</tr>
<tr>
<td></td>
<td>▪ If laparoscopy, desufflate</td>
</tr>
<tr>
<td>Beta-Blocker Overdose</td>
<td>▪ Glucagon 50 MICROgrams/kg IV, then 0.07 mg/kg/hour IV infusion</td>
</tr>
<tr>
<td></td>
<td>▪ Check blood sugar</td>
</tr>
<tr>
<td>Ca-Channel Blocker Overdose</td>
<td>▪ Calcium chloride 10-20 mg/kg IV or Calcium gluconate 50 mg/kg</td>
</tr>
<tr>
<td></td>
<td>▪ If ineffective, Glucagon at above doses</td>
</tr>
</tbody>
</table>

Instructions for PACING

1. Place pacing ECG electrodes AND pacer pads on chest per package instructions
2. Turn monitor/defibrillator ON, set to PACER mode
3. Set PACER RATE (ppm) to desired rate/min. (Can be adjusted up or down based on clinical response once pacing is established)
4. Increase the milliamperes (mA) of PACER OUTPUT until electrical capture (pacer spikes aligned with QRS complex; threshold normally 65–100mA)
5. Set final mA to 10mA above this level
6. Confirm pulse is present
**Bronchospasm**

<table>
<thead>
<tr>
<th>Intubated Patient</th>
<th>Non-Intubated Patient</th>
</tr>
</thead>
</table>
| - Increase FiO2 to 100%  
  - Auscultate the chest  
    - Equal breath sounds?  
    - Endobronchial ETT?  
    - Wheezing?  
  - Check the ETT  
    - Kinked?  
    - Secretions/blood in the ETT? Need for suctioning?  
  - Give inhaled albuterol with spacer, if available  
  - If BP and HR will tolerate, increase MAC% of sevoflurane  
  - For refractory bronchospasm, give ketamine 1-2 mg/kg IV  
  - If severe, consider intravenous epinephrine 1 mcg/kg IV  
  - Consider IV steroids  
  - Consider chest radiograph and lung ultrasound (see ‘Tension Pneumothorax’ card) | - Administer supplemental oxygen  
  - Auscultate the chest, differentiate from stridor/extrathoracic airway obstruction  
  - Give inhaled albuterol, if needed  
  - Consider chest radiograph  
  - Consider IV steroids  
  - If severe, consider intravenous epinephrine 1-2 mcg/kg IV  
  - If severe, consider ICU and/or advanced airway management. If ETT, go to ‘Intubated Patient’ column on this card (at the left) |

**Differential Diagnosis**

| URI/tobacco exposure  
| Foreign body  
| GERD  
| Mechanical obstruction of ETT  
  - Kinking  
  - Solidified secretions or blood  
  - Overinflation of tracheal tube cuff  
| Inadequate depth of anesthesia | - Pulmonary edema  
| - Tension pneumothorax  
| - Aspiration pneumonitis  
| - Pulmonary embolism  
| - Endobronchial intubation  
| - Persistent coughing and straining  
| - Asthmatic attack  
| - Anaphylaxis |
Cardiac Arrest: Asystole, PEA

- If ETT, 100-120 chest compressions/min + 10 breaths/min.
- If no ETT, 15:2 compression: ventilation ratio (100 chest compressions/min + 8 breaths/min)
- For chest compressions:
  - Place patient on backboard, maintain good hand position; if prone, see ‘Prone CPR’ card
  - Maximize EtCO₂ with force/depth of compressions
  - Allow full recoil between compressions
  - Switch with another provider every 2 min, if possible
  - Use sudden increase in EtCO₂ for ROSC. Do NOT stop compressions for pulse check

- Give 100% O₂. Turn off all anesthetic gases and infusions
- Obtain defibrillator. Attach pads
- Give epinephrine 10 MICROgrams/kg IV q 3-5 min
- Check pulse and rhythm (q 2 min during compressor switch)
- If no pulse and still not a shockable rhythm (asystole, PEA), resume CPR
- If a shockable rhythm (VF, VT): see next card ‘Cardiac Arrest: VF/VT’
- Check for reversible causes (Hs and Ts) early and often (see table below)
- If cardiac arrest > 6 min, activate ECMO (if available)

<table>
<thead>
<tr>
<th>Hs and Ts: Reversible Causes</th>

</tbody>
</table>
Cardiac Arrest: VF/VT

- Notify surgeon, call for help and code cart/defibrillator
- If ETT, 100-120 chest compressions/min + 10 breaths/min
- If no ETT, 15:2 compression:ventilation ratio (100 chest compressions/min + 8 breaths/min)
- For chest compressions:
  - Place patient on backboard, maintain good hand position; if prone, see ‘Prone CPR’ card
  - Maximize EtCO₂ > 10 mmHg with force/depth of compressions
  - Allow full recoil between compressions
  - Switch compressor every 2 min
  - Use sudden increase in EtCO₂ for ROSC, Do NOT stop compressions for pulse check
- Give 100% oxygen. Turn off anesthetics
- Obtain defibrillator. Attach pads. Shock 2-4 joules/kg (up to 10 joules/kg on subsequent shocks)
- Resume chest compressions immediately regardless of rhythm
- Epinephrine 10 MICROgrams/kg IV q 3-5 min while in arrest
- Check pulse & rhythm q 2 min during compressor change
- Check for reversible causes (Hs and Ts) early and often (see table below)
- Repeat sequence until return of spontaneous circulation
- Lidocaine 1 mg/kg bolus OR amiodarone 5 mg/kg bolus; may repeat (total of 2 doses)
- If cardiac arrest > 6 min, activate ECMO (if available)

### Hs and Ts: Reversible Causes

Cardiac Arrest: Prone CPR

**Children/Adeolescents**

- **If no midline incision:**
  Compress with heel of hand on spine and second hand on top

- **If midline incision:**
  Compress with heel of each hand under scapula

**Infants**

Compress with encircling technique:

- **If no midline incision:** thumbs midline

- **If midline incision:** thumbs lateral to incision

Figure 3: Original artwork by Brooke Albright Trainer, MD
Difficult Airway, Unexpected

- Increase $O_2$ to 100% and maintain continuous oxygen flow during airway management
- Call for help, airway expert and cart, rigid bronchoscope and tracheostomy kit
- If unable to mask ventilate, ask for 2-handed assistance and:
  - Insert oral and/or nasal airway;
  - If unsuccessful, insert supraglottic airway (e.g., LMA)
  - Decompress stomach with orogastric tube
- If able to re-establish pt spontaneous ventilation:
  - Consider reversing neuromuscular blocker with neostigmine/glycopyrrolate or sugammadex
  - Consider awakening pt if surgery not started
- Consider alternative approach for intubation (see table)
- If macroglossia (e.g. Beckwith-Wiedemann, Pierre-Robin), or mediastinal mass, consider prone or lateral position
- If still unable to ventilate:
  - Emergency non-invasive airway rigid bronchoscopy in younger children, jet ventilation in older children
  - Emergency invasive/surgical airway cricothyrotomy or tracheostomy

<table>
<thead>
<tr>
<th>Alternative Approaches for Intubation</th>

<td>• Blind oral</td>
</tr>
<tr>
<td>• Blind nasal</td>
</tr>
</tbody>
</table>
Simultaneously:
- Disconnect circuit from tracheal tube and remove tracheal tube
- Stop all gas flow ($O_2$, $N_2O$)
- Remove sponges and other flammable materials from airway
- Pour saline into airway

Re-intubate and re-establish ventilation
- If intubation difficult, don’t hesitate to obtain surgical airway

Consider bronchoscopy to assess for thermal injury
- Look for tracheal tube fragments
- Remove residual material

Impound all equipment and supplies for later inspection

Picture from ECRI: www.ecri.org
OR Fire (non-airway)

- Simultaneously:
  - Stop flow of medical gases
  - Remove drapes and all burning and flammable material from patient
  - Make one attempt to extinguish fire by pouring saline on fire

- If fire not extinguished on 1st attempt, use CO₂ fire extinguisher

- If fire persists:
  - **Activate fire alarm**
  - Remove patient from OR
  - Confine fire by closing all OR doors
  - Turn off O₂ gas supply to OR

- Maintain ventilation. Assess for inhalation injury
- Consider input from ENT, pulmonary, plastic surgery
- Consider PICU
- Impound all equipment and supplies for later inspection
Hyperkalemia

Serum K+ > 6 mEq/L

Treatment:

- If hemodynamically unstable, initiate CPR/PALS
- Hyperventilate with 100% O₂
- IV calcium gluconate 60 mg/kg or calcium chloride 20 mg/kg
  - Directly visualize site to avoid infiltration, flush tubing after calcium administration
- Stop K+ containing fluids (LR/RBC); switch to NS
- Dextrose IV 0.25-1 g/kg and insulin IV 0.1 Unit/kg
- Albuterol puffs or nebulized, once cardiac rhythm stable
- Sodium bicarbonate IV 1-2 mEq/kg
- Furosemide IV 0.5-1 mg/kg
- Consider terbutaline 10 MICROgrams/kg load, then 0.1-10 MICROgrams/kg/min
- If cardiac arrest > 6 min, activate ECMO (if available)
- Dialysis if refractory to treatment
- If transfusion required, use washed or fresh RBC

Causes of Hyperkalemia:

- Excessive intake: massive or “old” blood products, cardioplegia, KCl infusion
- Shift of K+ from tissues to plasma: crush injury, burns, succinylcholine, malignant hyperthermia, acidosis
- Inadequate excretion: renal failure
- Pseudohyperkalemia: hemolyzed sample, thrombocytosis, leukocytosis

Manifestations:

- Tall peaked T wave
- Heart block
- Sine wave
- V fib or asystole

From: Slovis C, Jenkins R. BMJ 2002
Acute Hypertension

- In pediatrics, hypertension is almost always treated by addressing likely causes such as light anesthesia or measurement error:
  - Ensure correct BP cuff size: cuff bladder width ~ 40% of limb circumference
  - Ensure arterial line transducer is at level of heart
- Consider placing arterial line if not already present

*CAUTION:* Anti-hypertensive drugs are almost never needed for routine pediatric cases. These medications are almost exclusively used for specialized cardiac, neurosurgical, or endocrine (pheochromocytoma) cases. Consult an expert before use.

* Numbers are only a guide and vary for individual patients and situations
**Hypoxia**

- Turn FiO$_2$ to 100%
- Confirm presence of end-tidal CO$_2$, look for any changes in capnogram
- Hand-ventilate to assess compliance
- Listen to breath sounds
- Check:
  - ETT tube position and patency. Correct if mainstem or supraglottic, suction to r/o mucous plug, secretions, or kink
  - Circuit integrity: look for disconnection, kinks
  - Blood pressure, pulse. If low, see appropriate card: hypotension, bradycardia, or cardiac arrest
  - Pulse oximeter: try new probe or changing placement
- If machine problem, consider using self inflating bag and oxygen tank
- Further assessment: Draw blood gas. Perform bronchoscopy, CXR, TEE, ECG
- Is airway cause suspected? (see appropriate table below)

<table>
<thead>
<tr>
<th>YES, Airway Cause IS Suspected</th>
<th>NO, Airway Cause IS NOT Suspected</th>

</tbody>
</table>
Increased Intracranial Pressure

- If GCS < 9, respiratory distress, hemodynamic instability:
  - Secure airway
  - Provide sedation prior to transport
  - Keep PaCO₂ 30-35 mmHg and PaO₂ > 60 mmHg
- Maintain cerebral perfusion pressure (CPP) > 50 mmHg
- Use vasopressors (phenylephrine or norepinephrine) as needed to maintain BP and CPP
- HOB at 30°
- Consider TIVA for anesthesia maintenance
- Give steroids as indicated
- Hypertonic saline (3% saline via central venous catheter) 1-3 mL/kg over 20 min, then 0.1-1 mL/kg/hour
  - Monitor serum sodium
  - Keep osmolarity < 360 mOsm/L
- Give mannitol 0.25-1 g/kg, to decrease ICP
- Consider seizure prophylaxis: Keppra (levetiracetam) 10 mg/kg IV
- **AVOID:**
  - Compression of neck vessels
  - Hyperthermia
  - Hyperglycemia & dextrose containing solutions (maintain glucose level < 200 mg/dL)
- Refractory elevated ICP treatment, consider:
  - Hyperventilation (PaCO₂ 28-35 mmHg)
  - Hypothermia (temperature 34°C)
  - Barbiturate coma
  - Paralysis with non-depolarizing agent
Local Anesthetic Toxicity

- Stop local anesthetic
- Request Intralipid kit
- Secure airway and ventilation
- Give 100% O₂

- Confirm or establish adequate IV access.
- Confirm & monitor continuous ECG, BP, and SaO₂

- Seizure treatment:
  - Midazolam 0.05-0.1 mg/kg IV
  - Be prepared to treat resultant hypoventilation

- Treat hypotension with small doses of epinephrine 1 MICROgram/kg

- Start Intralipid therapy (see inset box)

- If cardiac instability occurs:
  - Start CPR/PALS
    - Continue chest compressions (lipid must circulate)

**Avoid** vasopressin, calcium channel blockers and beta blockers

- Monitor and correct acidosis, hypercarbia and hyperkalemia

- Consider alerting nearest cardiopulmonary bypass/ECMO center and ICU if no ROSC after 6 min

---

**Intralipid Dosing**

- Bolus Intralipid 20% 1.5 mL/kg over 1 min
- Start infusion 0.25 mL/kg/min
- Repeat bolus every 3-5 min up to 3 mL/kg total dose until circulation is restored
- Increase the rate to 0.5 mL/kg/min if BP remains low or declines
- Continue infusion for 10 min after hemodynamic stability is restored.
- MAX total Intralipid 20% dose: 10 mL/kg over first 30 min
Loss of Evoked Potentials

- Notify all members of health care team. Call a “time out"

- Loss of evoked potentials (EP) requires definitive steps to re-establish perfusion/remove mechanical cause; MEP loss for > 40 min may increase possibility of long term injury
  - Assure the presence of attending surgeon, attending anesthesiologist, senior neurologist or neurophysiologist, and experienced nurse
  - Each service: review situation, report on management and corrective actions taken
    - Surgeon: rule out mechanical causes for loss/change
    - EP technologist: rule out technical causes for loss/change
    - Anesthesiologist: assure no neuromuscular blockade is present; reverse NMB if necessary

- Check patient positioning (neck, upper and lower extremities)

- Review the anesthetic and consider improving spinal cord perfusion by modifying:
  - Mean arterial pressure: maintain MAP > 65 mmHg using ephedrine 0.1 mg/kg IV and/or phenylephrine 0.3 - 10 MICROgrams/kg IV, with repeated doses as needed
  - Hemoglobin: if anemic, transfuse RBC to improve oxygen delivery
  - pH and PaCO₂: ensure normocarbia or slight hypercarbia (↑ I/E ratio, ↓ PEEP)
  - Temperature: ensure normothermia
  - Check for “unintended” drugs given (e.g. neuromuscular blocker)
  - Decrease depth of anesthetic

- Discuss feasibility of a useful wake-up test:
  - Patient is appropriate candidate if capable of following verbal commands

- Consider high-dose steroid if no improvement:
  - MethylPREDNISolone 30 mg/kg IV over one hour, then 5.4 mg/kg/hour IV for 23 hours
Malignant Hyperthermia

- Get MH Cart, dantrolene, and help
- Inform surgeon and stop procedure, if possible
- Stop volatile anesthetic, succinylcholine.
- Attach charcoal filter. Turn O₂ flow to 10 L/min
- Hyperventilate patient to reduce EtCO₂

- Give dantrolene 2.5 mg/kg IV, rapidly, through large bore IV if possible, every 5 min until symptoms resolve. May need up to 30 mg/kg
  - Dantrium/Revonto: Assign dedicated person to mix these formulations of dantrolene (20 mg/vial) with 60 mL non-bacteriostatic sterile water
  - Ryanodex: 250 mg is mixed with 5 mL non-bacteriostatic sterile water

- Transition to non-triggering anesthetic
- Give sodium bicarbonate 1-2 mEq/kg IV for suspected metabolic acidosis
- Cool patient if temperature > 39°C
  - Apply ice externally to axilla, groin and around head
  - Infuse cold saline intravenously
  - NG and open body cavity lavage with cold water
  - Stop cooling when temperature < 38°C

- Hyperkalemia treatment:
  - Calcium gluconate 30 mg/kg IV or calcium chloride 10 mg/kg IV;
  - Sodium bicarbonate 1–2 mEq/kg IV;
  - Regular insulin 0.1 units/kg IV (MAX 10 units) and dextrose 0.5 g/kg

- VT or afib treatment: Do NOT use calcium channel blocker; give amiodarone 5 mg/kg
- Send labs: ABG or VBG, electrolytes, serum CK, serum/urine myoglobin, coagulation
- Place urinary catheter, maintain UO > 2 ml/kg/hr.
- If cardiac arrest occurs, begin CPR & consider ECMO
- If no response after 10 mg/kg dantrolene, consider other dx: sepsis, NMS, serotonin synd., myopathy, pheochromocytoma
- Call ICU to arrange disposition. For post-acute management, see: http://www.mhaus.org

MH hotline 1-800-644-9737
Myocardial Ischemia

Treatment:

- Improve O\textsubscript{2} Supply:
  - Give 100% O\textsubscript{2}
  - Correct anemia
  - Correct hypotension
- Decrease O\textsubscript{2} Demand:
  - Reduce heart rate
  - Correct hypertension
  - Restore sinus rhythm
- Drug therapy:
  - Nitroglycerin 0.5-5 MICROgrams/kg/min
  - Consider heparin infusion 10 Units/kg bolus, then 10 Units/kg/hour

Potential Causes:

- Severe hypoxemia
- Systemic arterial hypo- or hypertension
- Marked tachycardia
- Severe anemia
- Coronary air embolus
- Cardiogenic shock
- Local anesthetic toxicity

Recognition

- ST depression >0.5 mm in any lead
- ST elevation >1 mm (2mm in precordial leads)
- Flattened or inverted T waves
- Arrhythmia: VF, VT, ventricular ectopy, heart block

Diagnostic studies

- 12-lead ECG:
  - II, III, aVF for inferior (RCA)
  - V5 for lateral ischemia (LCx)
  - V2, V3 anterior ischemia (LAD)
- Compare to previous ECGs
- Request Pediatric Cardiology consult and echocardiogram
Pulmonary Hypertensive Crisis

Mean PAP $>\$ Mean SAP

**Manifestation**
- Acute $↓$ O$_2$ sat, $↓$ BP, $↓$ EtCO$_2$, $↑$ CVP
- $↓$ Airway pressures from RV failure after abrupt pulmonary vasoconstriction
- RV diastolic hypertension $\rightarrow$ reduced LV filling and $↓$ cardiac output
- Bradycardia $\rightarrow$ Hypotension $\rightarrow$ Cardiac arrest

**Management**
- Give 100% O$_2$
- ASAP: Call for inhaled nitric oxide (iNO) 20-40 ppm
- Deepen anesthetic/sedation, administer narcotic, but avoid decreasing SVR.
- Consider using additional pulmonary vasodilators such as inhaled prostacyclin & IV milrinone
- Administer muscle relaxant
- Ventilation:
  - Use lowest PEEP necessary to maintain oxygenation, long expiratory phase
  - Ventilate with low airway pressures, but maintain adequate tidal volume to avoid atelectasis and preserve FRC
  - Hyperventilation to avoid hypercarbia
- Fluid management:
  - Use judicious fluid administration
  - Correct acidosis with sodium bicarbonate
  - Consider Plasmalyte rather than normal saline to reduce acid load
- Maintain coronary perfusion and treat RV ischemia
  - Administer norepinephrine, phenylephrine, vasopressin to maintain perfusion
  - Utilize pulmonary vasodilators as needed
- Maintain NSR and AV synchrony
- Temperature: ensure normothermia
- If cardiac arrest occurs, begin CPR and consider ECMO
- Call for defibrillator and code cart. Typically infant >220 bpm, child >180 bpm
- Place pt on backboard. Attach defibrillator pads
- Give 100% O₂, stop anesthetic agents, inform surgeon, consider cardiology consult

- If NO pulse present, start CPR/PALS; go to ‘Cardiac Arrest, VF/VT’ card
- If pulse present, administer appropriate treatment (see table below)

Tension Pneumothorax

- Stop N₂O; increase O₂ to 100%
- Secure airway with endotracheal tube
- Reduce positive ventilation pressure
- Consider lung ultrasound to confirm diagnosis (see inset)
- Administer vasopressors for circulatory collapse
- Perform immediate needle decompression, then chest tube placement
- Needle decompression:
  - 2nd rib space superior to 3rd rib, mid-clavicular line
    - 14-16g angiocath for teens/adults
    - 18-20g angiocath for infants/children
- Chest tube insertion
  - 5-6th intercostal space, mid-axillary line
- If no improvement in hemodynamics after a rush of air, consider:
  - Needle decompression of contralateral side
  - Presence of pneumopericardium
  - Scan both lungs with ultrasound to evaluate for alternate side or insufficiently decompressed pneumothorax

Lung Ultrasound Instructions

- High frequency probe, place longitudinally on chest, 2nd intercostal space. Slide probe downwards to observe pleural sliding
- If see pleural sliding, 100% PPV no ptx
- If no pleural sliding, consider pneumothorax, ARDS, fibrosis, acute asthma, pleurodesis
**Transfusion: Massive Hemorrhage**

- Notify Blood Bank immediately
  - Activate institutional pediatric massive transfusion protocol. Consider RBC : FFP : Platelets = 2:1:1 or 1:1:1
  - Use un-crossmatched O negative blood until crossmatched blood available
  - Consider intraoperative blood salvage (e.g., Cell Saver)

- Obtain additional vascular access if needed

- Watch for hyperkalemia, give calcium chloride or gluconate 30-50 mg/kg while directly visualizing site

- Warm the room

- Send labs/perform point of care testing q 30 min: CBC, platelets, PT/PTT/INR, fibrinogen, rapid TEG, ABG, Na, K, Ca, lactate

- Blood product administration:
  - Use 140 micron filter for all products
  - Use a blood warmer for RBC and FFP transfusion (NOT for platelets)
  - Consider use of rapid transfusion pumps
  - Monitor ABG, electrolytes, and temperature

- When under control: call blood bank to terminate

---

**Treatment**

- **HCT < 21% or Hgb < 7:**
  - 4 ml/kg PRBC increases Hct by 3

- **Platelet count < 50,000 (< 100K for brain injury), rapid TEG-MA < 54mm:**
  - 10 ml/kg apheresed platelets increases platelet count by 30 – 50k

- **INR > 1.5 (or > 1.3 brain injury), rapid TEG-ACT >120 sec:**
  - 10ml/kg thawed plasma increases coagulation factors by 20%

- **Fibrinogen < 100 mg/dL or rapid TEG-angle<66°, k value >120 sec:**
  - 10 ml/kg pooled cryoprecipitate increases fibrinogen by 30-50 mg/dL

- **Refractory hemorrhage**
  - Consider factor VIIa, up to 90 MICROgrams/kg
For All Reactions:
- Stop transfusion
- Disconnect donor product and IV tubing
- Infuse normal saline through clean tubing
- Examine blood product ID; determine correct pt
- Send product to Blood Bank

</table>
Set-up prior to patient arrival to OR:

- Assemble team and assign roles
- Estimate weight and prepare emergency drugs
- Gather equipment:
  - Airway supplies
  - Line placement and monitoring devices
  - Fluid warmer/rapid infusion device
  - Code cart with programmed defibrillator
- Type and cross blood products. Activate massive transfusion protocol if indicated

On patient arrival to OR:

- Maintain c-spine precautions for transport
- Secure/confirm airway (often aspiration risk, unstable c-spine)
- Ensure adequate ventilation (maintain PIP < 20 cm H$_2$O)
- Obtain/confirm large-bore IV access (central or intraosseous if peripheral unsuccessful)
- Assess hemodynamic stability. Pre-induction fluid bolus recommended if hypovolemic
  - 20 mL/kg LR or NS (repeat x 2) and/or 10 mL/kg RBCs or 20 mL/kg whole blood
- Arterial and central venous line placement if indicated
- Maintain normothermia
- Monitor and treat associated conditions
  - Anemia, coagulopathy, acidosis, electrolyte derangements
- Continuously assess for undiagnosed secondary and/or developing injuries, blood loss
