Musculoskeletal MR Imaging Lab (Gold)	45		

2011 Lucas Annual Report

Forward

The Richard M. Lucas Center was dedicated in June 1992 with a keynote address by Nobel Laureate Richard Ernst, a chemist credited with pioneering developments including Fourier Transform Nuclear Magnetic Resonance. With the Center now in its nineteenth year as a world-class focus of biomedical imaging research, and on the occasion of Gary M. Glazer stepping down as department Chair, it is appropriate to review some of the achievements of the Center over this period. It is entirely because of Gary’s vision, passion, and excitement for research that the Center was created and has become home for hundreds of scientists for periods of a few months to more than 19 years. During this time, thousands of research papers, books, and abstracts have been written, dozens of trainees have graduated, and many faculty careers have begun and flourished. A historical review as seen through Prof. Glazer’s Foreword comments in previous Annual reports is, therefore, especially timely. This year’s report is dedicated to Gary in grateful thanks for all that he has given to the Lucas Center, the Department, and the international biomedical imaging community. Following are edited snippets from selected annual reports.

- 1994

- Our proposal for the Center for Advanced MR Technology (CAMRT) is expected to be funded. This honor will bring substantial recognition and funding to the Lucas Center
 - In three years, the number of NIH-funded grants based at the Lucas Center has doubled
- 1995

The research environment in the coming year will become even more exciting as two major programs are developed:

 - An R&D program in interventional MRI that is a collaboration between Stanford and GE
 - An R&D program with Siemens using electron-beam CT, which is ten times faster than routine
- 1996

We have developed the following new programs and investigations:

 - A 3D laboratory in conjunction with several industrial partners and Stanford collaborators
 - fMRI applications move into the clinical environment
 - Advances in breast cancer imaging using MRI
- 1997

Expansion of the Center to include:

 - A high field MR program with the siting of a 3 Tesla magnet as an R&D effort was developed with GE
 - A 5-year program in advanced imaging of children is funded by the Packard Foundation
- 1999

Imaging studies now achieve a spatial resolution of 1 mm anywhere in the body and can be acquired very rapidly

 - A new program: We will be studying cost effectiveness and impact of our work on disease outcomes
- 2001

As we look forward to celebrating the Center’s 10-year anniversary, we have much to be proud of and tremendous enthusiasm for the next decade. We have created the intellectual and physical resources that have helped to transform medical imaging.
- 2002

During my recruitment to Stanford I spent a great deal of time dreaming about how we might achieve important innovations in medical imaging. Some ten years later, as I travel to different universities and hospitals, it gives me a great deal of pride to see techniques originally developed at the Lucas Center being used to improve health around the world.

 - Stanford approved our request for a major expansion, to include a very high field (7 Tesla) magnet and a cyclotron

Thank you *Gary*, and
Thank you, members of the
Lucas Foundation Board
from all of us

- 2003

- Molecular imaging program founded with recruitment of Sam Gambhir
- 2005

- Lucas expansion completed, more than doubling the size of the Lucas Center
 - NIH funding received for the in-vivo Cellular and Molecular Imaging Center (ICMIC)
- 2006

NIH funding received for the Center of Cancer Nanotechnology Excellence Focused on Therapy Response (CCNE-TR)
- 2007

The span of 15 years is an eternity in rapidly moving scientific disciplines such as imaging... What I can report is that the term “Lucas Center” is synonymous with excellence and innovation in imaging throughout the world.
- 2008

- Information Sciences in Imaging@Stanford (ISIS) section created
 - Canary Center at Stanford for Cancer Early Detection created
- 2010

- Renovation plans begun for replacement of 2 end-of-life scanners and siting of new program in PET/MR/13C Hyperpolarization
 - NIH-funded Center for Cancer Systems Biology (CCSB) created, augmenting existing centers CAMRT, ICMIC and the CCNE-TR

In summary, the Lucas Center has always been, and remains, an exciting, lively and dynamic nexus for fundamental and applied imaging research. All members of the RSL, MIPS, and ISIS programs with studies housed in the Center are deeply indebted to Gary Glazer for having his audacious dreams and making them come true. We are also deeply grateful to the Lucas Foundation for their generous and steadfast support over these nearly two decades.

Dr. Sanjiv Sam Gambhir is Appointed Chair

of the Department of Radiology

Sanjiv Sam Gambhir, MD, PhD

Please welcome Dr. Sam Gambhir, MD, PhD, as the next chair of the Department of Radiology. Dr. Gambhir was recruited to Stanford in 2003 to serve as Director of the then newly created Molecular Imaging Program at Stanford (MIPS) as well as Chief of the Division of Nuclear Medicine in the Department of Radiology.

Dr. Gambhir graduated from the Medical Scientist Training Program at UCLA, where he obtained his PhD in Biomathematics and MD in 1993. He trained in Nuclear Medicine at UCLA and is a Diplomate of the American Board of Nuclear Medicine. At UCLA he quickly rose from trainee to being Director of the Crump Institute for Molecular Imaging, Vice Chair of the Department of Molecular and Medical Pharmacology, and Professor of Molecular and Medical Pharmacology. He directed the activity of over 100 scientists at UCLA and was internationally recognized as a pioneer in helping to develop the field of molecular imaging. He moved over 35 scientists with him from UCLA to Stanford to build a multi-Departmental effort in molecular imaging. His laboratory has developed fundamental strategies to image cellular and molecular events for cancer detection and treatment with a focus on gene and cell therapies.

Since joining Stanford in 2003, Dr. Gambhir has developed a leading program in molecular imaging that developed unique collaborations and interactions across Stanford University and the world. He also designed and opened the new Nuclear Medicine & Molecular Imaging Clinic in late 2010 that brings state-of-art clinical care to adult and pediatric patients. He has recruited over 12 faculty to Stanford including 9 to the Department of Radiology. He successfully competed as PI for the NIH center grants In Vivo Cellular and Molecular Imaging Center (ICMIC) P50, Center for Cancer Nanotechnology Excellence (CCNE) U54, Early Detection Research Network (EDRN) U01, and Stanford Molecular Imaging Scholars (SMIS) R25T training grant. He also grew the Molecular imaging program from 35 to over 150 scientists.

Dr. Gambhir’s honors and awards for his work include the Taplin Award (2002), Holst Medal (2003), AMI Distinguished Basic Scientist of the Year Award (2004), SMI Achievement Award (2004), Doris Duke Distinguished Clinical Scientist Award (2004), Hounsfield Medal from Imperial College London (2006), Election as a fellow to the American Institute for American and Biomedical Engineering (2006), The Society of Nuclear Medicine Paul C. Aebersold Award (2006), Organized and Co-Chaired a Nobel Symposium in Stockholm (2007), Elected to the American Society of Clinical Investigation (2007), Tesla Medal from UK Royal College of Radiologists (2008), RSNA Outstanding Researcher Award (2009), Virginia and D.K. Ludwig Endowed Professorship (2009), and The Society of Nuclear Medicine George Charles de Hevesy Nuclear Pioneer Award (2011). He was also elected to the Institute of Medicine (IOM) of the US National Academy of Sciences as one of its youngest members, the highest honor possible for a physician.

Since 2004, he has served on the National Cancer Institute Scientific Advisory Board. He has over 400 publications including over 20 publications in the Nature series. He has edited several leading textbooks in the field, has 35 patents granted or pending, and has received over \$75 million in NIH funding as a principal investigator. He has given over 100 keynote talks including major international meetings and leading academic centers. He continues to actively engage the local community, and he raised significant gift funds to open the Canary Center at Stanford for Cancer Early Detection in 2009. Dr. Gambhir has significant experience with Industry and serves as an advisor for many companies including General Electric and Bayer. He serves on the scientific advisory boards of several companies including Visualsonics, MagArray, Spectrum Dynamics, Enlight, ImaginAB, and NinePoint Medical. He has also founded several new biotechnology companies including Endra and CellSight.

Dr. Gambhir is internationally recognized for his scientific contributions and for training and educating the new generation of physicians and scientists focusing on molecular imaging. While there is also no doubt that the field of radiology and imaging will change dramatically in the years ahead, Stanford will have Dr. Gambhir carrying on the tradition of excellence in radiology and imaging science.

We welcome Dr. Gambhir as our new Chair of the Stanford Radiology Department and wish him the best of success.

Overviews

Lucas Center Overviews

1989

2011

NIH Centers of Excellence

The Stanford Department of Radiology is home to four National Institutes of Health (NIH)-funded Centers of Excellence that contribute significant advances to improve health care for patients worldwide. In addition to technological, computational, biochemical, and biological innovation in the imaging sciences, we have trained more than 500 individuals since our first center was established in 1995. The following provides a short synopsis of each of these programs.

The National Center for Advanced Magnetic Resonance Technology at Stanford (CAMRT - P41)

The Center for Advanced Magnetic Resonance Technology at Stanford (CAMRT), led by Gary Glover, PhD, was established as a National Research Resource in 1995 and in 2010 began its 17th year as an NIH-funded center. This Center brings together the expertise and talent of individuals from the Radiology Department’s Richard M. Lucas Center for Imaging and the Electrical Engineering Department’s Magnetic Resonance Systems Research Laboratory. This multidisciplinary group shares the common goals of developing innovative Magnetic Resonance Imaging and Spectroscopy (MRI/MRS) techniques for fundamental anatomic, physiologic and pathophysiologic studies, and serving the academic and scientific community through collaborations, education, and access to Center facilities and resources. In addition to development of technology projects, the CAMRT provides support for collaborations and use of the facilities with users in the Radiology Department as well as more than 75 faculty and more than 200 other users from at least 14 departments. In addition, the innovative developments that emerge from this group are also shared across the U.S. and internationally. For further details, please see <http://rsl.stanford.edu/research/camrt.html> and the CAMRT/RSL Overview (page 6).

The In Vivo Cellular and Molecular Imaging Center at Stanford (ICMIC@Stanford - P50)

The ICMIC, directed by Sam Gambhir, MD, PhD, established in 2005 recently began its second cycle (2010) with an overall vision that emphasizes the application and extension of molecular imaging to translational research and clinical applications. While the ICMIC continues with its original goals to i) exploit molecular imaging by extracting basic information from animal models and pre-clinical studies, ii) provide new information on tumor diagnosis, initiation, progression, and responses to therapy, and iii) develop new imaging technologies, it now expands into clinical applications. The major goal for this new cycle is to provide the groundwork to integrate molecular imaging into translational studies that will move into clinical cancer applications. We will accomplish these goals by ensuring that basic scientists and clinician scientists are collaborating on ICMIC projects with well-defined end goals of clinical application. Additionally, ICMIC investigators form important scientific links to our NCI Funded CCNE U54 (Center for Cancer Nanotechnology Excellence) and NTR U54 (Network for Translational Research in Optical Imaging) programs through use of in vitro nanosensors and intraoperative microscopy, respectively. This will help to further accelerate our ability to bring important state-of-the-art solutions to cancer research and cancer patient care. For further details, please see <http://mips.stanford.edu/public/grants/icmic/> and the MIPS Overview (page 11).

The Center for Cancer Nanotechnology Excellence and Translation (CCNE-T - U54)

The Center for Cancer Nanotechnology Excellence and Translation (CCNE-T), led by Sam Gambhir MD, PhD, was approved for funding in 2010 and builds on the success of the CCNE-TR that was established in 2006. This new CCNE-T brings together scientists and physicians from Stanford University, University of California Berkeley/Lawrence Berkeley National Lab, University of California Los Angeles, University of Southern California, and the Massachusetts Institute of Technology. Our goals with the CCNE-T build on our vision that in vitro diagnostics, used in conjunction with in vivo diagnostics, can markedly impact cancer patient management. Through the use of nanotechnology we will significantly advance both in vitro diagnostics through proteomic nanosensors and in vivo diagnostics through nanoparticles for molecular imaging. The CCNE-T focuses markedly on bringing nanotechnology into clinical use. For further details of the CCNE, please see <http://mips.stanford.edu/public/grants/ccne/> and the CCNE Overview (page 14).

Cancer Center for Systems Biology (CCSB - U54)

The Stanford Cancer Center for Systems Biology (CCSB), led by Sylvia Plevritis PhD, is one of twelve National Centers for Systems Biology funded by the NIH and the NCI. The Center, located at Stanford University School of Medicine, represents a multi-disciplinary collaboration. Our Center represents a multi-disciplinary collaboration with its mission to promote the analysis of cancer as a complex system by merging experimental and computational methods. The Stanford CCSB aims to discover molecular mechanisms underlying cancer progression by studying cancer as a complex biological system that is driven, in part, by impaired differentiation. CCSB’s overarching goal is to provide a better understanding of the differentiation and self-renewal properties of cancer that will enable us to identify molecular therapeutic targets and strategies to eradicate this disease, or at least, maintain it in a nonlethal state. Our approach integrates high-throughput experimental datasets at the genomic, transcriptomic and proteomic levels, with novel computational techniques, in order to reveal critical molecular networks that drive cancer progression. Our multidisciplinary Center brings together faculty from the Schools of Medicine, Engineering, and Human Sciences, with expertise ranging from molecular biology and oncology to mathematics, statistics, and computer science. For further details of the CCSB, please see <http://ccsb.stanford.edu/> and the ISIS Overview (page 13).

Research Overview

Norbert Pelc, ScD, Associate Chair for Research
Susan Kopiwoda, MS, MPH, Director, Strategic Research Development

The Department of Radiology showed significant strength in the year 2011, maintaining its research programs in spite of a nationwide economic downturn and concerns over the NIH budget. Since 2004, NIH has averaged an approximate 2% increase in dollars budgeted/year not accounting for inflation; with a correction for inflation, NIH shows an average increase of 0% since 2004. To compound issues, while the NIH budget remains flat, the number of applications submitted to NIH steadily increases each year, thereby increasing competition and decreasing funding success rates. In spite of these odds, our progress this year has been excellent due to our researchers’ ability to develop outstanding proposals to obtain resources to support their research.

2011 Success: This year, our faculty, postdoctoral scholars, and research staff secured funding for 22 new or competitively renewed sponsored projects. Of these, 11 are new NIH funded projects, 5 of them R01/U01 programs. The awards include: 3 R01s (Bammer, Levin, Quon); 2 U01s (Gambhir, Plevritis); 2 R21s (Daniel, Daldrup-Link); 1 RC1 (Wu); 1 T32 (Pelc); 1 R25 (Gambhir); 1 S10 (Rutt); 2 DOE/DOA (Levin, Spielman); 1 CIRM (Rutt); 9 Industry or Foundation (Gambhir, Gold, Hoffman, Hovsepian, Marks). Our postdoctoral scholars have also been successful in recruiting funding. We are pleased to announce that two postdocs have been awarded K99 funding (Balchandani and Smith). It is also worth noting that Dr. Quon has achieved NIH investigator status with his first R01 awarded this year. We also have two other new investigators (Paulmurugan and Willmann) who are waiting for final funding decisions regarding their new NIH R01 programs.

A history of Stanford Radiology research funding from 2003 to 2011 is presented in Figure 1. In 2010 two large center grants, CCNE-TR and CCNE-T overlapped funding resulting in an unusually high awards total for 2010. If we correct for this unusual event we can demonstrate steady and strong growth in awarded research dollars from 2003 to 2011.

Our research success relies heavily on a strong base of funding requests. Figure 2 tracks our proposal history from 2004-2011 showing a consistent increase in the number of funding requests each year. The 2009 peak was due to a bolus of proposals submitted under the American Recovery and Reinvestment Act (ARRA) during that year. Other than 2009, we have increased the number

and dollars requested each year since 2006 and will continue that increase for the coming years due primarily to an increase in the number of faculty. There is on-going concern that the 2012 NIH budget will suffer significant cuts; this concern does not appear to have an effect on our proposal activity. We believe that in order to sustain and expand our programs, it is necessary to submit proposals of the highest quality, increase the number of grants submitted per year, explore sponsors other than NIH, and maintain and strengthen collaborations at all levels.

Personnel: This year we have added four new faculty and three new clinician-educators. See pages 20-21 for a short bio and photo of these faculty who already contribute to the clinical and research interests of the Department. Overall, our research group, including faculty, scientific staff, postdocs, graduate students, and administrative staff grew by 15% (from 250 to 287) this year.

Space: The Richard M. Lucas Center for Imaging is undergoing its third remodel to accommodate new and upgraded facilities, office space for new faculty, additional space for research, and space for students and staff associated with new programs.

Our off-campus research site on California Avenue, the Canary Center at Stanford, is close to full capacity. As we hire new faculty and expand our research, we continue an active dialogue with the University and Hospital leadership for facilities and space to support our programs.

In the next few pages, you will read about advances made by our NIH-supported Centers of Excellence, and the three Stanford Radiology sections that make up our research effort. These include: 1) the Radiological Sciences Lab (RSL), led by Gary Glover, PhD; 2) the Molecular Imaging Program at Stanford (MIPS), led by Sanjiv (Sam) Gambhir, MD, PhD; and 3) ISIS (Information Sciences in Imaging @ Stanford), co-led by Sandy Napel, PhD and Sylvia Plevritis, PhD. You will also find a complete listing of all of our sponsored projects on pages 185-192.

It is with continued support of the Lucas Family Foundation and the Canary Foundation that we are able to maintain leadership in research, train the next generation of imaging clinicians and scientists, and, above all, deliver the most advanced diagnostic and therapeutic techniques to benefit our patients and patients worldwide.

Fig 1. Funding for years 2003-11. The NIH total for 2011 is flat due to simultaneous funding of 2 CCNE Center grants in 2010. The CCNE awards overlap (one ending and one beginning) camouflages the outstanding success we are seeing for 2011 that includes awards for 11 new or competing NIH programs.

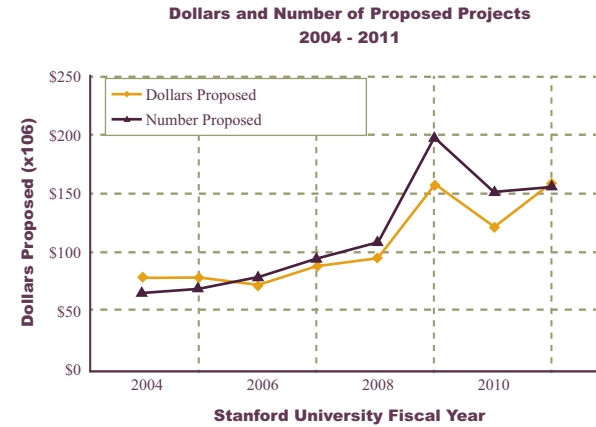

Fig 2. A steady increase in proposed funding from 2004 to 2011. The increase seen in 2009 was due to an unusual number of proposals submitted that year in response to US government stimulus dollars available.

RSL Overview

Radiological Sciences Laboratory and The Center for Advanced MR Technology (CAMRT)
Gary H. Glover, PhD, Director, Radiological Sciences Laboratory

The Lucas Center has been home to the Radiological Sciences Laboratory (RSL), a section of the Radiology Department, since the building’s dedication in 1992. In conjunction with the Electrical Engineering Department the RSL has hosted the Center for Advanced MR Technology, an NIH-funded National Research Resource since 1995. The Center also houses a cyclotron and radiochemistry labs as well as other wet labs for the Molecular Imaging Program under Dr. Sanjiv Gambhir. The Center’s state of the art imaging facilities support research of the RSL and others in the Radiology department as well as hundreds of on-campus and extramural researchers as a core facility. The Center has always been, and remains an exciting and lively nexus for fundamental imaging research.

THE RADIOLOGICAL SCIENCES LABORATORY

The RSL comprises 9 faculty, approximately 45 graduate and postdoctoral students, approximately 30 scientific staff and 6 administrative assistants, as well as the Lucas Center/RSL Administrative Services Director, Donna Cronister. These numbers represent a small increase in trainees over 2010.

The faculty serve in a wide variety of advisory roles to government and foundation agencies such as the NIH and in policy-making positions for international scientific societies such as the ISMRM and RSNA. Many of our faculty, scientific staff and students have garnered prestigious awards for their exceptional research achievements. Some of the faculty and their students’ activities of the past year are noted here.

THE NATIONAL CENTER FOR ADVANCED MR TECHNOLOGY AT STANFORD (CAMRT)

The CAMRT is a National Biotechnology Research Resource, sponsored by the NIH’s National Center for Research Resources (NCRR) with Dr. Glover as PI. The Center, initiated in 1995 as a close collaboration with Electrical Engineering, maintains the broad goal of developing and making available a spectrum of cutting edge MR imaging research tools for scientists who would otherwise not have access to such tools, as well as to train students and others in MRI. Over the years that goal has remained, as research projects have been introduced, matured and been replaced with new developments and opportunities. The grant is now in its 17th year of continuous funding. During its last 5 year renewal review in 2010 it received a perfect score (10) from the study section.

Outstanding progress has been made in all five of the core technology development areas that include RF pulse design, reconstruction methods (John Pauly, EE Department, core director), hardware (Brian Rutt, core director), body MRI techniques (Brian Hargreaves), neuro MRI (Gary Glover, with Mike Moseley and Roland Bammer contributing), and spectroscopic imaging development (Dan Spielman). Much of this exciting research is chronicled in the scientific reports that follow. These reports are acknowledged with funding from P41 RR009784.

Faculty and their Students’ Activities

Roland Bammer:

- Invited as member of BMIT NIH study group
- Proposed, and is now director of the Center for Functional Quantitative Neuroimaging This center is focused on translation of innovative imaging methods into clinical practice.
- Member of AMPC, JMRI editorial board, Chair of Publications committee, Chair of Motion Correction study group
- Research Associate, Stefan Skare, accepted faculty position at Karolinska hospital in Sweden

Rebecca Fahrig

- Serves on the Physics Advisory Board for Siemens AX
- Axiom research lab renovation underway with placement of the NIH awarded zeego system
- Erin Girard successfully defended her PhD thesis; now a Siemens Collaborations Manager
- Jared Starman, PhD, graduated Dec, 2010; now an Associate with Exponent, Inc.
- Arundhuti Ganguly, PhD, now an Associate at Varian

Brian Hargreaves:

- Awards:
 - Brian Hargreaves: NIH Edward Nagy New Investigator Award
 - Kyung Sung (finalist) for ISMRM poster award for Quantitative MRI of Breast Cancer
 - Christina Chen: SCBT/MR for MRI near Metallic Implants
 - Brian Hargreaves: ISMRM HM poster award for Metal-Induced MRI Artifacts
- Student Highlights:
 - Misung Han, PhD, graduated
 - Ernesto Staroswiecki defended PhD successfully
- Research translation:
 - Manoj Saranathan’s rapid DCE imaging being used clinically for Liver MRI
 - Imaging near Metallic Implants being used clinically for C-spine Neuroimaging

Faculty and their Students’ Activities

Michael Moseley:

- Editorial Boards:
 - Journal of Magnetic Resonance Imaging (JMRI)
 - Cerebrovascular Diseases (CD)
 - Journal of Cerebral Blood Flow and Metabolism (JCBFM)
 - International Journal of Stroke (IJS)
- Advisory Boards:
 - American Heart Association. AHA/ASA Stroke Council Writing Committee
 - (Definition of Stroke)
- Study section service
 - NIH Center for Scientific Review - Service on 6 study sections
 - NIH Center for Scientific Review - NIBIB ARRA P30 Review.

Kim Butts Pauly:

- Serves on the board of ISTU (International Society for Therapeutic Ultrasound)
- Director of CBIS (Center for Biomedical Imaging at Stanford)
- Two grad students received PhDs: Lena Keye, Andrew Holbrook
- Two trainees accepted faculty positions: Viola Rieke at UCSF and Peji Ghanouni at Stanford
- Student Juan Plata received an NSF graduate fellowship

Norbert Pelc:

- We obtained the first images from the Inverse Geometry CT scanner constructed under support from NIH and collaboration with GE.
- Submitted and awarded T32 training grant for doctoral students interested in biomedical imaging technology - funds 2 new students each for 2 years

Brian Rutt:

- Study Section Service:
 - Cancer Prevention and Research Institute of Texas, Interfaces Review Committee (IRC): permanent study section member
- New NIH Grants Funded:
 - NIH 1 S10 RR026361 (Rutt): Next Generation 7T MRI Platform Upgrade with Parallel Transmit Capabilities
 - NIH R01 AR054458 (PI: Daldrup-Link): Monitoring of Stem Cell Engraftment in Arthritic Joints with MR Imaging
 - NIH R21 AR059861 (PI: Daldrup-Link): Novel Imaging Approach to Monitor Chondrogenic Differentiation of iPS Cells
- New non-NIH Grants Funded:
 - GE (PI: Gold): Advanced MR Applications Development, Year 4
 - CIRM (Rutt): Development of Single Cell MRI Technology using Genetically-Encoded Iron-Based Reporters
- Prachi Pandit: awarded Stanford Molecular Imaging Scholars postdoctoral fellowship
- Jonathan Liu: awarded NSF Graduate Research Fellowship
- Jonathan Liu: awarded Stanford Graduate Fellowship

Dan Spielman:

- Two new grants: NIH K99/R00 (Balchandani): High Resolution Magnetic Resonance Imaging and Spectroscopy of Epilepsy at 7T
- DOD grant (Spielman): In Vivo Imaging of Branched Chain Amino Acid Metabolism in Prostate Cancer

Gary Glover:

- Awarded University of Minnesota’s Outstanding Achievement Award, 2nd highest UoM honor given.
- Grad student Catie Chang received PhD, will serve as postdoc at NIH (Jeff Duyn’s group).
- Postdoc Priti Balchandani received K99/R00 NIH fellowship award.

ISIS Overview

Information Sciences in Imaging at Stanford
Sandy Napel, PhD and Sylvia Plevritis, PhD, Co-Directors

The ISIS (Information Sciences in Imaging at Stanford) section of the Radiology Department is committed to harnessing the power that informatics can bring to imaging. This includes deriving new clinical and biological knowledge of normal and pathological processes, predicting clinical outcomes such as response to therapy and 5-year survival probability, and creating decision support applications. Researchers within ISIS collectively explore the full spectrum of information-intensive activities in imaging (e.g., image management, storage, retrieval, processing, analysis, understanding, visualization, navigation, interpretation, reporting, and communications) and in associated non-imaging domains (e.g., pathology, ophthalmology, oncology, molecular and genetic markers, family history, prior medical reports, and clinical outcomes). This is done by leveraging methods to extract computational and semantic features in images and integrate them with related clinical and molecular data.

The expertise of the ISIS faculty, staff, postdocs, and students spans image acquisition, image quantification, imaging informatics, knowledge engineering, bioinformatics, biocomputation, and systems biology. ISIS is co-led by Drs. Sandy Napel, Professor of Radiology, and Sylvia K. Plevritis, Associate Professor of Radiology, and includes core faculty David S. Paik, Assistant Professor of Radiology, and Daniel L. Rubin, Assistant Professor of Radiology. Our affiliate faculty member is Professor Robert J. Herfkens, whose expertise helps ISIS bridge between clinical imaging and information systems. ISIS, a highly collaborative group, has active projects with many of our Stanford faculty as well as around the world. ISIS administrative activities are handled by Administrative Program Manager Danae Barnes.

ISIS Core Resources

Critical to the ISIS mission is the development and application of new core resources to collect annotated imaging, clinical and molecular data, and to integrate them by creating databases and novel computational models that identify relationships among these data. In these areas, advancements over the past year include:

- Electronic Physician Annotation Device (ePAD):** ePAD, led by Dr. Rubin, is an open source tool enabling researchers and clinicians to identify and extract quantitative and semantic features (“imaging biomarkers”) from images, which include both “semantic annotations” on radiological images as well as quantitative features that algorithms extract from images (Figure 1). These metadata are stored in a standards-based syntax created by the cancer Biomedical Informatics Grid (caBIG) project. Semantic annotations enforce standardized terminologies such as RadLex and SNOMED. Currently, ePAD is being used in many ISIS projects where extract-

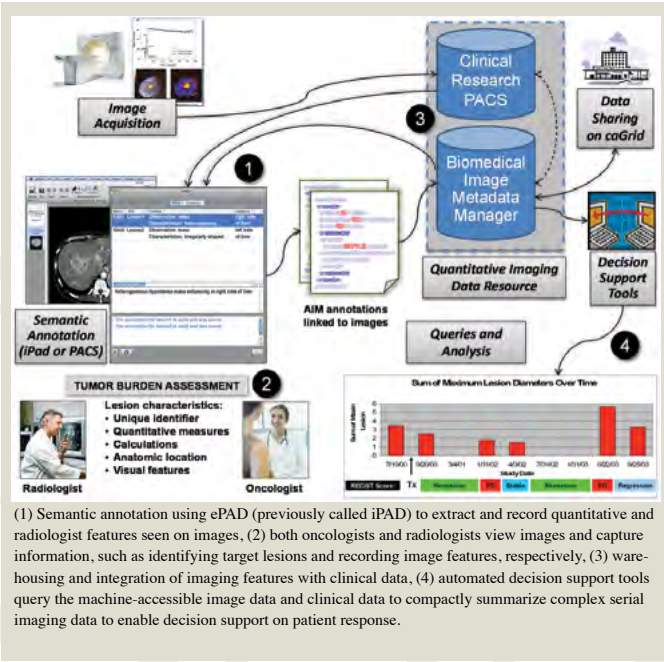

David Paik, Sandy Napel, Danae Barnes, Sylvia Plevritis, Daniel Rubin

ing semantic and quantitative features is required.

- Computational Methods and Resource for CT Liver Lesion Diagnosis and Discovery:** This project, led by Drs. Rubin, Beaulieu, and Napel, aims to build tools and methods for creating and mining databases of CT scans of liver lesions for knowledge discovery and eventual use in decision support through content-based image retrieval (CBIR) methods. A translational component is being pursued in collaboration with (and funded by) GE.
- Tools for Linking and Mining Image and Genomic Data:** Led by Drs.

Napel and Plevritis, this collaborative effort with Radiology Department members Daniel Rubin, Ann Leung, and Andy Quon, and Cardiothoracic surgeon Chuong Hoang, has begun to develop a radiogenomic map of non-small cell lung carcinoma that links image features to tumor gene expression, which in turn can be linked to prognosis and, potentially therapy response. The tools developed for integrating this genomic and imaging data can then be more broadly applied to other conditions where such data exists.

- RadBank Data Warehouse:** RadBank/RadTF, led by Dr. Rubin, is an integrated data warehouse that brings together radiology reports with pathology and clinical information (and in the future, molecular data) to enable researchers, clinicians, and educators to find cases of particular imaging findings, diagnoses, modalities, and other information. To date, the RadTF component is being used extensively by all clinical faculty in the department to identify teaching cases, to perform retrospective research, and to identify cohorts for new research.
- Imaging Biomarker Ontology (IBO):** The Paik Lab has developed an initial draft of the Imaging Biomarker Ontology and is working to refine and expand this knowledge resource to cover

(1) Semantic annotation using ePAD (previously called iPad) to extract and record quantitative and radiologist features seen on images, (2) both oncologists and radiologists view images and capture information, such as identifying target lesions and recording image features, respectively, (3) warehousing and integration of imaging features with clinical data, (4) automated decision support tools query the machine-accessible image data and clinical data to compactly summarize complex serial imaging data to enable decision support on patient response.

Figure 2: Algorithm (A) results (B, C) of automated quantitative imaging methods to detect and quantify cancer lesions on follow-up CT images of cancer patients.

the domain of how quantitative imaging measurements are captured from imaging data, with an emphasis on molecular imaging. IBO is being used to enable intelligent and semantically-searchable warehousing of quantitative measurements from molecular imaging analogous to the way in which microarray data is currently captured in public databases, thereby enabling imaging to realize its potential in translational bioinformatics research. One collaboration for the deployment of IBO is with the FDA and NIST to create a system for benchmarking quantitative imaging biomarkers.

- Standards for Interchange of Nanoparticle Data:** As part of a national working group in collaboration with the NCI's caBIG, ASTM, and Pacific Northwest National Labs, the Paik Lab has been developing computational standards for the leading nanoparticles used for diagnostic imaging and/or therapeutic delivery. These efforts have helped guide development of caNanoLab, the NCI's repository of nanoparticle characterization data, the adoption of the NanoParticle Ontology (NPO) as a standard and the development of Nano-TAB, a data exchange format for nanomaterial composition and characterization.

ISIS Research Grants

- Modeling the Role of Differentiation in Cancer Progression:** In one of twelve national Centers for Cancer Systems Biology funded by the NIH, Dr. Sylvia Plevritis directs a \$12.8 million dollar, 5-year multidisciplinary program to study the role of differentiation in hematologic malignancies. This program integrates a diversity of high-throughput data, including genomic, transcriptomic, and proteomic, to elucidate molecular networks driving cancer progression and treatment response. More information about CCSB can be found at <http://ccsb.stanford.edu>.
- Computerized Quantitative Imaging Assessment of Tumor Burden:** Dr. Rubin is Principal Investigator of one of the centers in the newly established Quantitative Imaging Network (QIN), composed of researchers who will develop approaches to validate and standardize imaging data and related imaging metadata for quantitative measurements of responses to cancer therapies. Stanford's part of the QIN will be to create computer algorithms to measure tumor burden in patients, and to identify and quantify novel imaging biomarkers that can provide earlier indications of treatment response to cancer therapies (Figure 2).
- Simulation Modeling of Breast Cancer Health Care Policies:** Dr. Plevritis has been a Principal Investigator of the NCI CISNET breast cancer program over the past ten years has received an additional 5 years of funding to mathematically model the impact of alternative cancer control policies on breast cancer incidence and mortality. Currently, her research

Figure 3: System diagram for “Tools for Linking and Mining Image and Genomic Data in Non-Small Cell Lung Cancer” project. All data gets stored in our database, including a research PACS for DICOM images, and BIMM for storage of metadata. Processing occurs using OsiriX and Definiens, platforms for image manipulation and quantitation, respectively. Results of processing go back to BIMM, from which they can be mined for discovery and decision support.

Figure 4: Sample radiogenomics mapping of NSCLC, linking gene expression to image features. (A) One particular gene cluster (genes along rows, samples along columns), with gene expression encoded high (red) vs. low (green), functionally annotated to represent molecular changes in the extracellular matrix, particularly TGF-beta regulated genes. (B) Metagene of cluster; (C) Computed “compactness” CT feature: low (yellow) vs. high (blue) compactness; (D) Example CT images of compactness: high (top) and low (bottom)

program focuses on the role of MRI screening, particularly in the high risk population, the impact of postmenopausal hormone therapy on past breast cancer trends, and the impact of biomarker-specific screening and treatment interventions on future trends.

- Simulation Modeling of Lung Cancer Health Care Policies:** Dr. Plevritis has been a Principal Investigator of the NCI CISNET lung cancer program, which over the past five years has received an additional 5 years of funding to mathematically model the impact of alternative CT screening policies on lung cancer incidence and mortality. Currently, her research program focuses on translating the results of the National Screening Trial (NLST) to the population level, in collaboration with investigators from CISNET and NLST.
- Integration of Imaging and Molecular Phenotypes for Improved Management and Understanding of Lung Cancer:** This project, supported in part by a grant from General Electric Medical Systems and led by Drs. Napel and Plevritis, has made significant progress. With the goal of integrating medical imaging and molecular features from lung cancer patients who undergo surgical resection, we have curated and correlated databases containing features from cross-sectional imaging exams (CT and PET) and gene expression of the human tissue specimens (Figure 3) to create a radiogenomics map of NSCLC (Figure 4). By leveraging our radiogenomics map of NSCLC with public databases linking gene expression to survival, we have created the first results suggesting that survival can be predicted from imaging alone (Figure 5). These pilot data have been submitted to the National Cancer Institute and a larger project is now awaiting funding.
- Computerized Quantitative Imaging Assessment of Age-Related Acute Macular Degeneration (AMD):** Dr. Rubin is Principal Investigator of a Bio-X Interdisciplinary Initiatives Program grant which fosters a new collaboration between Ophthalmology and Radiology (a novel intersection even outside Stanford) to exploit the expertise in imaging informatics in ISIS to tackling challenges and opportunities in the domain of retinal imaging (Figure 6). The specific goal of the project is to develop quantitative imaging methods to assess disease burden, prognosis, and treatment response in patients with

ISIS Overview (continued)

Information Sciences in Imaging at Stanford
Sandy Napel, PhD and Sylvia Plevritis, PhD, Co-Directors

- AMD, and in the the future, with other retinal diseases. The methods being developed have mutual benefits to imaging analysis methods in both radiology and ophthalmology.
- **Quantitative imaging assessment of breast cancer:** Dr. Rubin is Principal Investigator of a Stanford Cancer Center Interactive Project Grant to develop quantitative imaging informatics methods to characterize patients with breast cancer. The project is developing tools and methods to analyze perfusion MRI data in breast cancer and to discover computational imaging biomarkers that differentiate patients who respond to treatment from those who fail to respond. The quantitative methods aim to be generalizable to other types of cancer and to be useful in other ISIS projects.
 - **Cancer Nanotechnology Knowledgebase for Nanoparticle Analysis and Design:** Dr. Paik is Principal Investigator of a Driving Biological Project sub-contract from the National Center for Biomedical Ontology to build a powerful new toolset for information retrieval for cancer nanotechnology-related information using biomedical ontologies. This project aims to develop computational representations of nanoparticle structure that will be used to develop search queries across a variety of relevant nanomedicine online resources.

Strategy for the creation and application of the NSCLC radiogenomics map. Step 1 integrates the CT and PET/CT image and the gene microarray data from our study cohort. Step 2 maps the metagenes to publicly available microarray data with survival. Step 3 links image features expressed in terms of metagenes to public gene expression data.

ISIS Affiliated Programs

ISIS is closed affiliated with the following two programs in the Department of Radiology:

- **3-Dimensional and Quantitative Imaging Laboratory (3DQ Lab):** The 3DQ Lab applies and delivers innovative techniques for efficient quantitative analysis and display of medical imaging data to the Stanford community. The co-directors are Drs. Sandy Napel and Brooke Jeffrey, both Professors of Radiology. More information about 3DQ Lab can be found at <http://3dradiology.stanford.edu>.
- **Systems Biology Discovery Lab:** ISIS has acquired a Systems Biology Discovery Lab that will enable experimental validation of computationally derived results; this lab is located in LUCAS P169 and is under the supervision of Dr. Plevritis. New work in the laboratory is focused on understanding the tumor microenvironment by integrating molecular and imaging data.

Summary

Through the efforts described above, we believe that ISIS has made progress that will enable the realization of its three main goals: (1) an evidenced-based diagnostic decision support system, whereby patient-specific images, clinical data and, if available, molecular data, can be compared to the database to suggest the most likely diagnoses, prognoses, and most relevant treatments, (2) biological discovery, i.e., synthesis and potential testing of hypotheses regarding the underlying biology in the development, progression and hopeful eradication of specific diseases, and (3) the translation of these developments into clinical practice using computers and image storage systems that are ubiquitous in healthcare enterprises today.

(A) Cross sectional optical coherence tomography (OCT) image of the retina in a patient with AMD showing distortion of the retinal pigment epithelium (bright band) by abnormal drusen which have been automatically segmented and quantified by our computational method. (B) Selective slab summed voxel projection image produces a novel visualization of drusen analogous to that seen by ophthalmologist when examining the eye, but with drusen enhancement through image processing. (C) quantitative analysis of drusen morphology from which numerous quantitative features about drusen are extracted, so that in (D) quantitative features such as volume of disease burden can be tracked and correlated with treatment response.

<http://isis.stanford.edu>

MIPS Overview

Molecular Imaging Program at Stanford
Sanjiv S. Gambhir, MD, PhD, Director, Molecular Imaging Program at Stanford

The Molecular Imaging Program at Stanford (MIPS) continues to experience significant growth. Many faculty within the Department of Radiology and from other Departments continue to help build the program. The MIPS structure is also supported by two recently renewed NCI programs, the In vivo Cellular Molecular Imaging Center (ICMIC) P50 and the Center for Cancer Nanotechnology Excellence (CCNE) U54, which help to advance projects in the Radiology Department, the School of Medicine, across the Stanford campus, and nationwide at a number of academic centers. Very recently we have learned that our NCI-funded R25 postdoctoral training program, the Stanford Molecular Imaging Scholars (SMIS), which was originally funded in 2006 to train the next generation of cancer molecular imaging post-doctoral scholars, will be funded for an additional 5 years. We also participate in an NIH post-doctoral training grant (T32) for cardiovascular molecular imaging, which is in its third year. In addition, all labs continue to grow with new faculty, new students, post-doctoral fellows, and outstanding research staff joining the program. Also, many visiting scientists from around the world visit our program to learn more about molecular imaging.

Regarding new projects funded during 2011, Dr. Gambhir has been awarded an NCI Early Detection Research Network (EDRN – U01) to conduct research on the early detection of prostate cancer. Dr. Gambhir has also been newly awarded by the Ben and Catherine Ivy Foundation to develop a research program in neuro-oncologic clinical imaging. On the positron emission tomography (PET) front, Dr. Levin leads a new program in preclinical translation of new scintillation light detection concepts for PET. Also on the PET front, Dr. Quon now leads an NIH R01 that evaluates a PET tracer (18F-fluorothymidine (FLT)) for the purpose of therapy monitoring for lymphoma patients. Dr. Rutt, whose interests combine MRI and molecular nanotechnology, was awarded a CIRM technology grant and an NIH shared instrumentation grant. Dr. Daldrup-Link has received an R21 for her research in applying nanoparticles (ferumoxytol) to detect tumor associated macrophages in breast cancer. This year, we also have three investigators receiving their first NIH R01 grants. Dr. Quon now leads a clinical trial study to evaluate a new PET tracer; Dr. Willmann will develop microbubble probes for breast cancer early detection; and Dr. Paulmurugan will study tamoxifen resistance in breast cancer. In addition, Dr. Bryan Smith, a graduate of our SMIS R25 program, has recently been awarded his first NIH award, a K99. All of these new projects, along with ongoing projects are listed in the Appendix (Funded Research Projects).

Through the Canary Foundation's efforts to develop a new center for early cancer detection, we continue to build bridges with many investigators on campus. Our off-campus space on California Avenue, acquired in 2010 and now at capacity, facilitates our cancer early detection efforts. We are convinced that more investments are needed in the earlier detection of all disease, including cancer. Detecting disease earlier allows a much better potential for cure. The Canary Center works on novel in vitro diagnostics

(e.g., using patient blood samples) as well as new imaging strategies with high sensitivity to detect very low disease burden. It is hoped that in the next 3-5 years Stanford will become a world-leader in the important field of early cancer detection.

We continue to have several seminar series on campus to help educate scientists about molecular imaging. The molecular imaging seminar series (http://mips.stanford.edu/public/mi_seminar.adp) is now in its sixth year and has a large collection of videos available on-line of speakers from the last few years. Students from different MIPS labs now routinely present as well. The Nanobiotechnology seminar series (http://mips.stanford.edu/public/nanobiotech_seminar.adp), which focuses on new applications of nanotechnology to cancer, continues to draw attendance for faculty from all over campus. Several speakers from around the country have already presented in the series and all lectures are available on-line.

MIPS now has 55 faculty members with 24 full members and 31 associate members. While many MIPS members are from the Department of Radiology, overall our program attracts faculty from all over campus representing more than 25 different disciplines. The number of graduate students, MSTP students, post-doctoral fellows, research scientists, technicians, and administrative staff continues to grow and is currently approximately 175. Although we have experienced a significant increase in personnel with the Canary Center for Cancer Early Detection, with the addition of new faculty this year, we anticipate that number to continue increasing.

Our new Molecular Imaging/Nuclear Medicine clinic became fully operational late last year with a grand opening in September 2010. This advanced facility with its spectacular design and up to date equipment consolidates all of the PET-CT, SPECT-CT, and SPECT imaging systems with related equipment in one location. The new radiochemistry facility, also at this location, is currently pending design approval. Newer cardiac and optical imaging equipment will also be placed in this new clinic. And for our advanced pre-clinical research, we have designed the clinic so that large animal imaging experiments can be performed there. Research trials that combine state-of-art imaging with in vitro diagnostics (e.g., blood proteomics) are also now possible in this new facility.

An important link in the MIPS research chain focuses on industrial partnerships with key leaders in the molecular imaging community. Several projects to develop new imaging agents/strategies are underway with General Electric Global Research, General Electric Healthcare, Schering-Plough, Bayer-Schering, and GlaxoSmithKline. It is likely that additional industrial partners will enter into collaborative research relationships over the next several years. These relationships are key to our goals to translate discoveries at Stanford to the patient bedside. Several faculty are also involved in new startup-company efforts with intellectual property from their laboratories at Stanford. These include new efforts in diagnostics, small animal imaging and clinical imaging.

<http://mips.stanford.edu>

Canary Center Overview

Sanjiv Sam Gambhir, MD, PhD, Director
Daniela Starcevic, PhD, Deputy Director

The Canary Center at Stanford for Cancer Early Detection celebrated its second anniversary in June 2011. The mission of the Canary Center, which occupies ~30,000 square feet of the building at 1501 S. California Ave, is to lead and foster research programs leading to the development of blood and imaging tests for the early detection of lethal types of cancer. The Center represents a novel alliance between the Canary Foundation, the Department of Radiology, the Cancer Center, and the School of Medicine. The Center also actively fosters intellectual and programmatic alliances with the Schools of Engineering & Humanities and Sciences.

The Center's mission is based on the striking association between early cancer diagnosis and improved survival rates: the chances of survival are far greater when cancer is detected in its earliest stages, while still localized to the organ of origin and amenable to treatment. To optimize the detection of cancer at this stage, the Center is taking a binary approach including 1) identifying blood biomarkers that can be detected by simple blood screening tests and developing clinically translatable screens for these biomarkers, and 2) developing molecular imaging tests to confirm and localize early cancerous lesions. The extraordinary technical challenges associated with this dual strategy include the refinement of molecular imaging agents to specifically detect pre-invasive malignant tumors the size of a blueberry (< 5 mm). They also include the development of proteomic approaches that can reliably detect minute (< 0.1 ng/ml) quantities of cancer-specific proteins released into the bloodstream by these small lesions. Cost-effective solutions are expected by applying a relatively cheap blood test followed by a more expensive imaging study, although in some cases the blood test and the imaging test will be performed concurrently. Having both approaches will also likely lead to a greater overall accuracy.

To accomplish these goals, the Center was specifically designed to house state-of-the-art core facilities and collaborative research programs in molecular imaging, proteomics, chemistry, and bioinformatics. The Proteomics Core facility houses cutting-edge mass spectrometry platforms dedicated to the discovery and validation of blood and tissue protein biomarkers. The Chemistry Core is engaged in the specific design and refinement of molecular imaging agents for early detection, which then undergo preclinical testing using in vivo and ex vivo model systems, including patient blood and tissue samples. The Molecular and Cell Biology Core works closely with both the Proteomics and Chemistry Cores to screen and refine agents that can bind cancer-specific targets in tissues and thus complements the efforts of the Chemistry and Proteomics Cores to develop blood and imaging tests for cancer early detection. A significant effort has been put forward over the past year to equip the Center cores and laboratories with state-of-the-art instrumentation to promote and facilitate innovative research efforts. Three new mass spectrometers are already in place and the acquisition of additional ones is planned.

CANARY CENTER AT STANFORD

Collaborative research efforts fostered at the Center are made possible by creating a truly multidisciplinary team of faculty members. Current faculty members focus on imaging technologies, chemistry, and disease mechanisms/cell biology. Two new faculty members were recruited to the Center to fulfill two out of the 8 billets committed by the Stanford School of Medicine. Dr. Sharon Pitteri is particularly interested in breast and ovarian cancers and focuses on identifying and characterizing biomarkers for cancer risk, diagnosis, progression, and recurrence. Additionally, the Pitteri group is working toward identifying tissue biomarkers for imaging applications. Dr. Parag Mallick is interested in integrated computational and experimental systems-biology approaches to uncover circulating and cell-surface proteins useful for early cancer detection. Dr. Mallick's lab develops rigorous dynamic systems models of tumor and host behavior, and validates those models by large-scale measurements in both animal model systems and clinical samples.

Canary Center research programs are actively interfacing with other facilities and programs on campus, including MIPS and CCNE-TR, in order to leverage the latest developments in molecular imaging and nanotechnology into the early detection effort. Collectively, these initiatives form a direct pipeline for the translation of early cancer detection into clinical trials and practice.

A specific example of a novel molecular imaging strategy that is expected to help the goal of early cancer detection is ultrasound with targeted microbubbles. These gas filled microbubbles can be chemically coupled to targeting ligands that allow the bubbles to bind to tumor vasculature. This will allow molecular imaging using a conventional anatomical imaging strategy (ultrasound). This is expected to allow detection of tumors in the 3-5 mm range. A specific example of a novel strategy being pursued for blood biomarker detection is based on magnetonanoarrays being developed as part of the Stanford CCNE-TR. This novel technology allows the detection of many different biomarkers at levels that are 10-100 fold better than the most sensitive ELISA tests currently available.

The National Cancer Institute (NCI) Early Cancer Detection Network (EDRN) has recently awarded a major U01 grant to the Canary Center team. Under the leadership of Drs. Sam Gambhir and James Brooks (Department of Urology), this project will further examine the microbubble and magneto-nanoarray technologies as they apply to prostate cancer early detection and enable the first clinical trial using this technology. Many exciting new developments for early cancer detection are on the horizon and will be pioneered by the Center. The past year was marked by an aggressive effort to bring additional funding into the Center through both private foundations and government funding. Decisions regarding the outcome of several pending grant proposals are expected in the upcoming months.

As we head into the upcoming year, our goals include recruiting several new faculty members in the area of bioinformatics and in vitro and in vivo diagnostics, building up the Biorepository Core which will store and organize human samples for research efforts headed by the Center, and pursuing a number of other funding opportunities.

<http://canarycenter.stanford.edu>

CCSB Overview

Center for Cancer Systems Biology
Sylvia K. Plevritis, PhD, Director

The Stanford Center for Cancer Systems Biology (CCSB) is one of twelve Centers for Systems Biology funded by the NCI's Integrative Cancer Biology Program. The Stanford CCSB aims to discover molecular mechanisms underlying cancer progression by studying cancer as a complex biological system that is driven, in part, by impaired differentiation. Increasing evidence indicates that many cancers, like normal tissue, are composed of a hierarchy of cells at different stages of differentiation, and that the disease is maintained by a self-renewing subpopulation. Our overarching goal is to provide a better understanding of the self-renewing properties of cancer that will enable us to identify molecular therapeutic targets and strategies to eradicate this disease, or to maintain it in a nonlethal state.

Our biological projects are integrated with novel computational techniques, designed to dissect processes and causal factors underlying impaired differentiation as a driver of cancer progression in several hematologic malignancies. In order to identify mechanistic underpinnings of cancer progression, we believe that a network-based and multiscale viewpoint is needed. Increasingly, diseases such as cancer are recognized as resulting from disruption in the coordinated performance of a complex biological system. This systems biology viewpoint necessitates the incorporation of high throughput, high dimensional data, and development of computational methods specifically geared to its analysis. We aim to develop three essential and interlocking requirements for a comprehensive systems analysis of cancer. First, powerful methods are required to infer molecular regulatory networks that drive phenotypic processes such as differentiation. Second, computational approaches are needed that can identify and isolate underlying patterns of progression in cancer, which can then be related to underlying regulatory networks. Third, executable models are desirable so that it is possible to pose hypothetical "what if" questions to predict how, for example, a targeted intervention might affect the subsequent course of disease. These computational approaches are

applied to the study of differentiation in a range of hematological malignancies. In fact, our Research Plan is divided among 4 research projects (see Figure 1). Project 1 is dedicated to developing novel computational methods, whose applications are deeply integrated into our three complementary experimental projects in AML (Project 2), FL (Project 3), and

T-ALL (Project 4). Taken as a whole, the four projects will provide a systems-level, network-focused view of the role of differentiation in cancer. Our integrative approach will enable us to ascertain differences between these hematologic malignancies, and commonalities, which may generalize to other cancers.

The Stanford CCSB faculty brings clinical and basic cancer researchers together with researchers from mathematics, information technology, imaging sciences, and computer science to work on key questions in cancer biology. The CCSB core faculty includes PI Sylvia K. Plevritis, PhD, Associate Professor of Radiology, co-PI Garry Nolan, PhD, Professor of Microbiology & Immunology, Daphne Koller, PhD, Professor of Computer Science, David Dill, PhD, Professor of Computer Science, Ronald Levy, MD, Professor of Medicine (Oncology), Ravindra Majeti, MD, PhD, Associate Professor of Hematology, Dean Felsher, MD, PhD, Lead, Associate Professor of Medicine (Oncology) & Pathology.

Our CCSB also maintains a Core for Data Integration, which is lead by Andrew Gentles, PhD, CCSB Scientific Program Manager and includes Rob Tibshirani, PhD, Professor of Health Research and Policy (Biostatistics) and Ramesh Nair, PhD. The purpose of this Core is to facilitate interactions between computational projects and experimental projects, and to ensure timely dissemination of resources. The core also provides initial processing of complex data sets, and dissemination of them and computational tools developed in their analysis. We aim to make all data, software, and results generated by the Stanford CCSB readily available to all researchers. Our CCSB Data Portal is coming soon!

Our CCSB operations are lead by Anita Samantaray, MPH, Program Manager, who also coordinates our outreach and education efforts. The Stanford CCSB produces education and outreach programs for students at all levels. Public outreach activities and research experiences enhance CCSB's impact in the bay area. We continue to offer annual symposia and monthly seminar series on campus to help educate scientists about cancer systems biology. The CCSB seminar series (<http://ccsb.stanford.edu/events/seminars.html>) is now in its second year and its Video Gallery can be viewed online (http://ccsb.stanford.edu/events/video_gallery.html).

Figure 1. Organization of CCSB research projects.

<http://ccsb.stanford.edu>

CCNE Overview

Center for Cancer Nanotechnology Excellence
Sanjiv Sam Gambhir, MD, PhD, Director, and Demir Akin, DVM, PhD, Deputy Director

Stanford University is home to two large consortia, the Center for Cancer Nanotechnology Excellence focused on Therapy Response (CCNE-TR, <http://mips.stanford.edu/grants/ccne>) and the Center for Cancer Nanotechnology Excellence and Translation (CCNE-T, <http://mips.stanford.edu/grants/ccne-t>). Both Centers are funded through the National Cancer Institute (NCI) and composed of prominent US universities, non-profit organizations, and for-profit groups. These two projects, collectively referred to as the CCNE, operate simultaneously and fall under the School of Medicine's larger parent program Molecular Imaging Program at Stanford (MIPS), which is led by Dr. Sanjiv Sam Gambhir. The original Center was funded in 2006 (CCNE-TR); the competing renewal (CCNE-T) was awarded in October 2010 for an additional 5 years. The CCNE brings together scientists, engineers, and physicians from different disciplines including chemistry, materials science, engineering, radiology, molecular biology, cancer biology, and oncology. The CCNE-TR consortium includes leading scientists and physicians from Stanford University, University of California Los Angeles (UCLA), University of Southern California (USC) and the Fred Hutchinson Cancer Research Center (FHCRC). The CCNE-T consortium includes Stanford University, University of California Berkeley (UCB), Lawrence Berkeley National Lab (LBNL), UCLA, USC, and the Massachusetts Institute of Technology (MIT). The names of a few of the CCNE members include Drs. Sanjiv Sam Gambhir (PI), David Agus, Demir Akin (CCNE Deputy Director), Paul Alivisatos, Jonathan Berek, Alice Fan, Dean Felsher, Samir Hanash, Luke Lee, Parag Mallick, Scott Manalis, Martin McIntosh, Ed Myers, David Paik, Steve Quake, Jianghong Rao, Brian Rutt, Robert Sinclair, Mark Stolzowicz, Mary Tang, Shan Wang (Co-PI of CCNE-T), Irv Weissman, Robert Wilson and Anna Wu. These Centers leverage several activities in cancer biomarker discovery and validation efforts within the Canary Foundation and the Canary Cancer Early Detection Center at Stanford. The CCNEs and the Canary Center share the common assumptions that: 1) in vitro diagnostics used in conjunction with in vivo diagnostics can markedly impact medical care and management for cancer patients; and 2) nanotechnology can significantly advance in vitro diagnostics through proteomic nanosensors as well as in vivo diagnostics through nanoparticles for molecular imaging. Although we are broadly interested in all types of cancers, our primary cancer concentrations are on lung and ovarian and secondarily on

Image 1: A summary of the performance of the CCNE-TR and CCNE-T.

brain, prostate and colorectal cancers. Our Centers highly leverage resources at the Stanford Bio-X and Nanoscale Science and Engineering Programs, the California Nanosystems Institute, and the Cancer Centers of Stanford, UCLA, USC and Fred Hutchinson. We also rely on resources at several small companies (most of these are CCNE outgrowths) and General Electric as well as other industrial partnerships to accelerate clinical translation of our technologies. We are also tightly connected with several long running Cancer trials and patient sample repositories so that our results are rapidly applicable to cancer patient use. Thanks to the significant investment in our center from Stanford University, the School of Medicine, the Department of Radiology, the Stanford Cancer Center, the Lucas Foundation, and the National Cancer Institute (NCI), our CCNEs are rapidly growing both in their research scope and physical boundaries. A brief summary of our exemplary success is shown in Figure 1. Twenty-nine provisional patents have been filed by our investigators and six spin-off companies were founded within the past 5 years. These companies are: MagArray Inc. (Dr. S. Wang, Magneto Nano Sensors), ImaginAB (Dr. A. Wu Engineered Antibodies for Diagnostics), Zymera Inc. (Dr. J. Rao/S.S. Gambhir, Self-Illuminating Quantum Dots for Diagnostics and in vivo imaging), Endra Inc. (Dr. S.S. Gambhir, Photoacoustic Imaging), Nine Point Medical (Dr. S.S. Gambhir, Raman imaging for the GI tract), CellSight (Dr. S.S. Gambhir, Small Molecule and Nanoparticle Strategies for imaging Cell Trafficking in Patients).

Our cancer and nanotechnology research not only results in high impact publications but also inspires and guides the entire relevant biomedical community. With our four research projects and four supportive cores within the CCNE-T, we are focusing on the development of novel next generation smart nanoparticles includ-

Image 2: An advanced clinical Raman endoscope being developed within the CCNE-TR and CCNE-T for colorectal cancer.

The CCNE uses magnetic nanoparticles in clinical diagnostics and therapy. This image reveals the trajectories of fluorescently labeled magnetic nanoparticles under a rotating magnetic field gradient.

The CCNE uses special microscopes to study the targeting of nanoparticles to tumor blood vessels and to individual tumor cells (red). In this image, the white spots are single-walled carbon nanotubes that have been chemically linked to molecules that selectively target the cancer cells (green). These nanotubes can be used to diagnose and kill tumors.
Bryan R Smith, PhD and Sanjiv Sam Gambhir, MD, PhD

ing Raman and self-assembling nanoparticles, the application of our maturing magneto-nanotechnology platform in blood proteomics and cell sorting, and the use of multiple other nano-platforms to interrogate single circulating tumor cells in a unique way that exists only at Stanford. We also focus on molecular imaging of ovarian cancer with photoacoustics and Raman nanoparticles, and monitoring response to therapy using imaging and magneto-nanosensors. Several of our nano-enabled research products are at an advanced development stage, thanks to the excellent staff, nanofabrication, and nanocharacterization infrastructure at Stanford. One such product is our clinical Raman Endoscope instrument being developed through the CCNE-T. Endoscopic imaging has proven to be an invaluable diagnostic tool with its ability to non-invasively assess deep tissues within the body and has played a key role in the screening of colon cancer and is credited with the decline in deaths due to prevention through the early removal of cancerous polyps. However, conventional white light endoscopy only offers physicians real time structural detail with little physiological information. We have developed an accessory Raman endoscopic probe that has the potential to provide real time functional information during routine endoscopy at unsurpassed sensitivity levels and multiplexing capabilities that did not exist until now. This novel approach would allow endoscopists to distinguish between normal and cancerous tissues instantly, as well as to identify flat lesions that are easily missed during conventional screening endoscopy.

In the CCNE-T program, our multidisciplinary scientists and physicians use nanotechnology to create the tiniest of devices (one billionth of a meter in size) that will enable us to eventually screen individuals by a simple blood test. By then performing an analysis and using imaging, we will be able to find problem cells and simultaneously eradicate or treat those cells successfully before they have grown out of control. Through use of today's advanced nanotechnology materials and molecular biology techniques for earlier detection and treatment monitoring, we expect to dramatically improve cancer survival rates and provide reassurance to patients that their treatment is effective. With our highly interactive and cohesive program focused on developing and validating nanotechnology for anti-cancer therapy response and earlier cancer detection, we will continue to imagine, invent, and innovate for the benefit of cancer patients.

2011 Graduates

Murat Aksoy, PhD	Research Associate, RSL	Stanford University
Catie Chang, PhD	Postdoctoral Fellow	NIH
Misung Han, PhD	Postdoctoral Fellow	UCSF
Andrew Holbrook, PhD	Research Associate, RSL	Stanford University
Jared Starman, PhD	Associate	Exponent Engineering & Scientific Consulting
Adam de la Zerda, PhD	Postdoctoral Fellow, Chemistry	UC Berkeley

2011 Transitions

Didem Aksoy, PhD	Staff Scientist, RSL	Stanford University
Anca Dragulescu-Andrasi, PhD	LSRA	Stanford University
Arun Ganguly, PhD	Senior Scientist	Varian Medical Systems
Pejman Ghanouni, MD, PhD	Assistant Professor, Radiology	Stanford University
Erin Girard	Collaborations Manager	Siemens Corporate Research
Ben Hackel, PhD	Assistant Professor	University of Minnesota
Sam Mazin, PhD	President	RefleXion Medical
Jennifer Prescher, PhD	Assistant Professor, Chemistry	UC Irvine
Viola Rieke, PhD	Assistant Professor	UCSF
Stefan Skare, PhD	Faculty	Karolinska Institute
Bryan Smith, PhD	Staff Scientist, MIPS	Stanford University
Matus Straka, PhD	Senior Research Associate, RSL	Stanford University
Tau Xu, PhD	Associate	Citadel Investment Group

New Clinical and Research Faculty

Pejman Ghanouni, MD, PhD, Body MRI Section

Dr. Pejman Ghanouni will join the Department of Radiology as an Assistant Professor in the Body MRI Section on January 1, 2012. Following completion of his undergraduate training at Harvard, Dr. Ghanouni acquired his MD and PhD in the Medical Scientist Training Program (MSTP) at Stanford. For his PhD research he used biophysical techniques to investigate the mechanism of activation of the beta-2 adrenergic receptor, a model G protein coupled receptor. Dr. Ghanouni served as Chief Resident while at Stanford, and also was awarded a Radiological Society of North America (RSNA) Trainee Prize in 2009 for his research using MRI to monitor the role of macrophages in the development of chronic pain behavior. As a National Cancer Institute Fellow, Dr. Ghanouni is studying clinical and preclinical applications of MR-guided focused ultrasound surgery. Dr. Ghanouni is a co-Principal Investigator on two human clinical trials using focused ultrasound to palliate painful bone metastases.

Amelie Lutz, MD, PD, Musculoskeletal Section

Amelie M. Lutz, MD, PD, was appointed as an Assistant Professor in the Department of Radiology in the Musculoskeletal (MSK) section on May 2, 2011. Dr. Lutz has been a clinical instructor and clinician researcher in radiology and molecular imaging since 2009. After completing medical school and internship in Internal Medicine/Endocrinology at the Albert-Ludwigs-University in Freiburg, Germany, Dr. Lutz did her residency in Diagnostic Radiology at the University Hospital in Zurich, Switzerland and a fellowship in Body Imaging/Musculoskeletal Imaging at the Kanton Hospital in Frauenfeld, Switzerland. In 2008 she received the *venia legendi* (member of the academic faculty, PD) in Diagnostic Radiology for her work in the field of kinematic and cellular-targeted MR imaging at the University of Zurich. Her research interests include the development of novel diagnostic strategies for early detection of cancer, especially of ovarian cancer. She is currently working on preclinical and translational studies including multimodality strategies using blood biomarker tests and molecular imaging for ovarian cancer early detection as well as on the translation of these strategies into clinical pilot studies.

Parag Mallick, PhD, Molecular Imaging Program at Stanford (MIPS)

Dr. Mallick joined the department of Radiology as an Assistant Professor of Radiology in the MIPS section on January 1, 2011. He completed his undergraduate degree in Computer Science and Biochemistry at Washington University (St. Louis, MO), after which he obtained his PhD in Chemistry & Biochemistry at UCLA. For his doctoral research, Dr. Mallick performed whole-proteome structure and function studies and investigated protein networks. Dr. Mallick then joined Dr. Ruedi Aebersold's group at the Institute for Systems Biology where he performed fundamental studies of proteomics technologies and developed clinical proteomics workflows to study cancer and neurodegenerative diseases. Dr. Mallick was also faculty at USC and UCLA where he focused on experimental and computational systems biology and proteomics. In his current role as a member of the Canary Center at Stanford for Cancer Early Detection, he focuses on 1) systems-based studies to develop quantitative models of the states and trajectories of cancer cells, and 2) remote-sensing models that describe how to infer those states and trajectories via measurements of the circulation. By combining these two areas of inquiry, the Mallick lab hopes to develop a strategy to rationally identify molecular indicators for lung cancer, prostate cancer, and lymphoma.

Sharon Pitteri, PhD, Molecular Imaging Program at Stanford (MIPS)

Dr. Pitteri joined the Department of Radiology as an Assistant Professor of Radiology in the MIPS section on November 1, 2010. After completing her undergraduate degree in chemistry at Carleton College (Northfield, MN), she obtained her PhD in chemistry from Purdue University (West Lafayette, IN). Dr. Pitteri joined Dr. Sam Hanash's laboratory as a post-doctoral research fellow in the Public Health Sciences division at the Fred Hutchinson Cancer Research Center (Seattle, WA), where she applied advanced proteomic technologies to molecular diagnostics. As a member of the Canary Center at Stanford for Cancer Early Detection, the Pitteri Lab is focused on discovering and validating novel molecular indicators for breast cancer and ovarian cancer and looks forward to opportunities for collaborations.

New Clinical Educators

We also welcome new Clinical Instructors whose primary and critical role is to provide excellence in radiological clinical care, teaching, and institutional service appropriate to their training and clinical interest areas. Please welcome our new clinical instructors whose commitment and dedication to patient care are highly valued and provide critical service and discipline in all clinical areas of the Department of Radiology.

Bao Do, MD, Musculoskeletal Radiology Section

Dr. Bao Do joined the faculty in July 2011 as a Clinical Instructor after completing his subspecialty fellowship in Musculoskeletal Radiology at Stanford. He received his BS/BA in Biochemistry and Economics with honors at UC Davis as a University of California Regents Scholar and his MD at the University of Illinois. He began his training at the University of Iowa and completed his Diagnostic Radiology Residency at Stanford. His clinical interests include musculoskeletal MRI, natural language processing, and designing information retrieval and computer decision support systems in Radiology. Dr. Do is a co-developer of rad TF, a Radiology domain semantic search engine, with Dr Andrew Wu, MD and Dr Daniel Rubin, MD.

Rajesh Shah, MD, Interventional Radiology Section

Dr. Rajesh Shah joined the Radiology faculty as a Clinical Assistant Professor in August 2011. He received his BS (magna cum laude) in Electrical Engineering from the University of Illinois at Urbana-Champaign. He worked in web development before going to medical school at The University of Chicago. He completed his internship at California Pacific Medical Center followed by a residency in diagnostic radiology at the University of Illinois at Chicago Medical Center. He did a fellowship in Vascular and Interventional Radiology at Stanford. Dr. Shah worked at Memorial Sloan Kettering Cancer Center before joining the faculty at Stanford as Chief of Interventional Radiology at the Palo Alto Veterans Administration Health Care System. His interests include chemoembolization, bland embolization, selective internal radiation therapy, lung and liver ablation, and arterial and venous interventions.

David Wang, MD, Interventional Radiology Section

Dr. David Wang joined the faculty in 2011 as a Clinical Instructor. He completed fellowship training in Vascular and Interventional Radiology at the University of Pennsylvania Medical Center as the Constantin Cope-Cook Medical Fellow preceded by residency training in Diagnostic Radiology at Stanford. He received his medical degree from Stanford University School of Medicine, where he was an HHMI research fellow and the lead founder of Stanford's Pacific Free Clinic. Dr. Wang earned his undergraduate degrees at Stanford University, graduating with honors and distinction in Biological Sciences and Economics. His clinical interests include interventional oncology, minimally invasive treatment of arterial and venous diseases, and endovascular management of dialysis accesses. His research interests include therapeutic applications of molecular imaging, use of interventional techniques to advance molecular and cell-based therapies, targeted gene and drug delivery, tissue engineering, and device design and development.

Faculty Awards

Recipient	Award
Scott Atlas, MD	2011 University of Chicago Distinguished Alumni Achievement Award nominee
Scott Atlas, MD	2011 University of Illinois Alumni Achievement Award Distinguished Alumni
Scott Atlas, MD	2011 University of Illinois Liberal Arts and Sciences Distinguished Alumni
Scott Atlas, MD	Member, Nominating Committee, Nobel Prize in Medicine and Physiology; 2004 – 2010
Roland Bammer, PhD	Senior Fellow, Freiburg Institute of Advanced Studies (FRIAS), University of Freiburg, Germany
Sandip Biswal, MD	2010 Resident Teaching Award: Junior Faculty of the Year
Zhen Cheng, PhD	Certificate of Recognition: Siemens Competition Mentor
Zhen Cheng, PhD	Cover page article of Bioconjugate Chemistry 22(3)
Zhen Cheng, PhD	Cover page article of Small 6(10)
Heike Daldrup-Link, MD	Editor's Recognition Award with special distinction for reviews for the journal Radiology
Heike Daldrup-Link, MD	Elected member of the Board of Directors of the Society for Pediatric Radiology
Bruce Daniel, MD	Finalist, Young Investigator Award competition. 2010 International Society for Magnetic Resonance in Medicine. “A Pilot Study Comparing Blood Oxygen Level Dependent (BOLD) Contrast in the Human Healthy and Malignant Breast”
Dominik Fleischmann, MD	2011 Society of Gastrointestinal Radiologists Wyle J. Dodds Research Award: "Prognostic Value of Early Changes in Liver Metastases Treated with Bevacizumab determined with Dynamic Contrast Enhanced CT"
Sanjiv Sam Gambhir, MD, PhD	Society of Nuclear Medicine's 2011 Georg Charles de Hevesy Nuclear Pioneer Award for "extraordinary contributions to the field of molecular imaging"
Garry Gold, MD	2011 Allan V. Cox Medal for Faculty Excellence in Fostering Undergraduate Research
Garry Gold, MD	Fellow, International Society of Magnetic Resonance in Medicine
Garry Gold, MD (Chen, Christina)	SCBT/MR Young Investigator Award: "Improved Methods for MR Imaging Around Metallic Implants: Artifact Assessment and Clinical Impact"
Garry Gold, MD	SNM Correlative Imaging Council Walter Wolf Award: "Correlation Between MRI and NaF PET/CT in Patients with Patellofemoral Knee Pain"
Garry Gold, MD (Lauren Shapiro)	Stanford Firestone Medal for Excellence in Undergraduate Research - mentor to Ms. Lauren Shapiro
Brian Hargreaves, PhD	General Electric “Thought Leader” Award, May 2010 for “Reducing Metal Artifacts”
Brian Hargreaves, PhD	ISMRM HM Poster Award for "Metal-Induced MRI Artifacts"
Brian Hargreaves, PhD	NIH Edward Nagy New Investigator Award, April 2011
Lawrence Hofmann, MD (Stefanie Carr)	2010 Dr. Constantin Cope Medical Student Society of Interventional Radiology Annual Scientific Meeting Research Award – Mentor for Stephanie Carr.

Recipient	Award
Lawrence Hofmann, MD (Keith Chan)	2011 Dr. Constantin Cope Medical Student Society of Interventional Radiology Annual Scientific Meeting Research Award – Mentor for Keith Chan
Lawrence Hofmann, MD	Ohio State School of Medicine Early Career Achievement Award
Lawrence Hofmann, MD	The Society of Interventional Radiology elected fellow
Andrei Iagaru, MD	Best Essay Award, ACNM Annual Meeting: “Classical Hodgkin Lymphoma in First Complete Remission: Is There a Role for 18F FDG PET/CT Surveillance?”
Andrei Iagaru, MD	Research featured on AuntMinnie.com and SNM News Highlights
Andrei Iagaru, MD	Winner – Young Professionals Tournament, 1st Sino-American Conference on Nuclear Medicine
Aya Kamaya, MD	2011 Society of Gastrointestinal Radiologists Wyle J. Dodds Research Award: "Prognostic Value of Early Changes in Liver Metastases Treated with Bevacizumab determined with Dynamic Contrast Enhanced CT"
Aya Kamaya, MD	2011 SUR Research Award. Society of Uroradiology for grant application: "Photoacoustic Imaging of Bladder Cancer"
Nishita Kothary, MD	Committee member, Interventional Radiology (VIR) board certification for Exam of the Future (EOF), American Board of Radiology
Nishita Kothary, MD	Elected to the Society of Interventional Radiology Fellowship (FSIR) for Outstanding Contribution to the Field of Interventional Radiology
Nishita Kothary, MD	Invited member to the American Association of Physicists in Medicine Task Group 199 - Implanted Target Surrogates for Radiation Treatment Verification
William Kuo, MD	Dr. Gary J. Becker Young Investigator Award – Society of Interventional Radiology Foundation.
William Kuo, MD	Outstanding Faculty Award – Society of Interventional Radiology.
William Kuo, MD	SIR Dr. Gary J. Becker Young Investigator Award for Most Outstanding Clinical Science Research Paper
William Kuo, MD	Society of Interventional Radiology elected fellow
Craig Levin, PhD	Physics in Medicine and Biology Featured Article by Editors of Institute of Physics, selected for "novelty, high level of interest and potential impact on future research"
Margaret Lin, MD	2010 Stanford Radiology Clinician Educator of the Year
Andrew Quon, MD	2011 Image of the Year - Society of Nuclear Medicine
Hans Ringertz, MD, PhD	RSNA Special Presidential Award: "Significant Contributions to the Field of Radiology or the Radiologic Sciences"
Daniel Rubin, MD, MS	2010 caBIG Connecting Collaborators Award, National Cancer Institute
Daniel Rubin, MD, MS	AMIA Distinguished Paper Award: "Natural Language Processing for Lines and Devices in Portable Chest X-Rays"
Daniel Rubin, MD, MS	caBIG® Connecting Collaborators Award
Daniel Rubin, MD, MS	RSNA Cum Laude Award: "Natural Language Processing in Radiology"

Faculty Awards

Recipient	Award
Juergen Willmann, MD	2011 Society of Gastrointestinal Radiology Roscoe E. Miller Award: Best Paper presentation
Joseph Wu, MD, PhD	Receives the CIRM Basic Biology Award
Joseph Wu, MD, PhD	2010 White House Presidential Early Career Award for Scientists & Engineers (PECASE)

Postdoctoral and Trainee Awards

Recipient	Award
Priti Balchandani, PhD	K99/R00 Pathway to Independence Award: High Resolution Magnetic Resonance Imaging and Spectroscopy of Epilepsy at 7T
Keith Chan, MS	SIR Constantin Cope Medical Student Award: Common Iliac Vein Stenosis: A Risk Factor for Oral Contraceptive-induced Deep Vein Thrombosis
Christina Chen	SCBT/MR Young Investigator Award: Improved Methods for MR Imaging Around Metallic Implants: Artifact Assessment and Clinical Impact
Nick Conley, PhD	BioX Interdisciplinary Initiatives Program grant
Nick Conley, PhD	Awarded the Cardiovascular Institute's Younger Fellowship Award for: High-Throughput Mutagenesis of Neuropilins to Elucidate Domains Required for Hedgehog Signaling
Jing-yu Cui	Awarded an HHMI Fellowship
Jing-yu Cui	Received the Pan Wen-Yuan Foundation Scholarship for outstanding academic performance
Aloma D'Souza, PhD	AACR Poster Award for: A Novel Method of Tumor Characterization by Protein and microRNA Biomarker Release Using Ultrasound
Jessica Faruque, MS	SIIM research grant: Developing a Scalable Similarity Reference Standard for a Content-based Image Retrieval (CBIR) System
Eugene Gu	Awarded an HHMI Fellowship
Aileen Hoehne, PhD	Wiley Award for the International Symposium on Radiopharmaceutical Sciences (ISRS) in Amsterdam for best submitted abstract
Aileen Hoehne, PhD	Received the Wiley Award from International Symposium for: Radiolabeling of a Saxitoxin derivative for PET/MRI imaging of pain
Susan Koppmann, PhD	SNM Poster Award in Oncology for: Characterization of 177Lu-Affibody-HSA bioconjugate for radionuclide therapy of EGFR-expressing head and neck carcinomas
Albert Hsiao, MD, PhD	ARRS Residents in Radiology President's Award: Fast Pediatric Cardiac MR Flow and Ventricular Volume Assessment
Shijun Hu, PhD	2010-12 American Heart Association Postdoctoral Fellowship
Frances Lau, PhD	Selected as Institute of Physics Journal's Featured Article for: Analog signal multiplexing for PSAPD-based PET detectors: simulation and experimental validation
Andrew Lee	2010-13 Bio-X Graduate Student Research Fellowship
Jonathan Lu	NSF Graduate Research Fellowship

Postdoctoral and Trainee Awards

Recipient	Award
Jonathan Lu	Stanford Graduate Fellowship
Hua Fan-Minogue, MD, PhD	Cover Article PNAS for: Noninvasive molecular imaging of c-Myc activation in living mice (PNAS, 2010)
Divya Nag	2010 American Heart Association Summer Fellowship
Kazim Narsinh	RSNA Research Medical Student Grant: Imaging Human Induced Puripotent Stem Cell-derived Cardiomyocyte Transplants
Patricia Nguyen, MD	2010-12 ACC/GE Healthcare Career Development Award
Juan Plata	NSF Graduate Fellowship
Prachi Prandit, PhD	Stanford Molecular Imaging Scholars Postdoctoral Fellowship
Guillem Pratx, PhD	BCRP Fellowship Award
Laura Sasportas, MS	Awarded an HHMI Fellowship
Conroy Sun, PhD	BCRP Fellowship Award: X-ray Luminescent Nanophosphors for Breast Tumor Detection and Treatment
Kyung Sung, PhD	Finalist for ISMRM Post Award for Quantitative MRI of Breast Cancer
Li Wang, PhD	2011-13 American Heart Association Postdoctoral Fellowship
Huaijun (Morgan) Wang, MD, PhD	Stanford Dean's Fellowship Award
Yanmei Yang, PhD	Cover Picture/Article: Enzyme-Responsive Multifunctional Magnetic Nanoparticles for Tumor Intracellular Drug Delivery and Imaging (Chem. Asian J. 6/2011)

Our group photo represents approximately half of the Radiology research personnel found in various locations on the medical school campus.

Advanced Techniques for Cancer Imaging and Detection - T32

PI: Gary M. Glazer, MD
Program Manager: Donna Cronister/Lanzie Rivera

The Department of Radiology at Stanford University offers qualified individuals a unique research opportunity through our Advanced Techniques for Cancer Imaging and Detection Program, which began its 19th year of training on March 1, 2011. The goal of our program is to provide MD and PhD research fellows training in cancer-related imaging research. Fellows have the opportunity to work with our world-renowned faculty who are committed to sharing their knowledge and mentoring future leaders in radiology. Our program allows basic scientists in medical imaging (PhD) and clinical scientists (MD post-residency) to collaborate in an unparalleled environment that combines medical imaging sciences, clinical sciences, a strong cancer focus, and an institutional commitment to training academic radiologists and basic scientists in imaging science. We are preparing a competing renewal application for this program in January 2012 as our current funding will end on February 28, 2013.

A specific aim of our training program is to position our trainees for a career in academic radiology. To date, we have graduated 32 trainees from our program. Of these 32 alumni, 23 have taken positions in academia; 3 in industry and 6 are in private practice. Our trainees continue to be extremely productive. We often collaborate with them in their new positions both locally and throughout the country. We are grateful to the National Institutes of Health for its recognition of the strength and success of our training program.

Currently we have 5 trainees in the program: Drs. Dragos Constantin, Sarah Geneser, Pejman Ghanouni, Catherine Moran, and Bhayva Shah. Dr. Grace Tye ended her two year fellowship on June 30, 2011 and joined a private practice radiology firm in La Jolla, California. On July 1, 2012, two clinical fellows will join the program, both specialize in body imaging. Current trainees and their research interests are summarized briefly below.

Current NCI T32 Postdoctoral Trainee Research Interests

Dragos Constantin, PhD joined RSL as an NCI fellow in 2009. His research interests involve theoretical and experimental investigation of the magnetic resonance imaging integration with a medical linear accelerator to provide real-time image guidance to target temporally changing tumor anatomy, particularly for cancers in the thorax and abdomen. Dr. Constatin began his second year of training with Dr. Rebecca Fahrig in February 2010 and is working closely with faculty in the Department of Radiation Oncology.

Sarah Geneser, PhD, joined the RSL group as an NCI fellow in 2011. In 2010 Dr. Geneser was awarded the highly competitive Dean’s Postdoctoral Fellowship award from the Stanford School of Medicine. During this fellowship year, her goals focused modeling the impact of hormone replacement therapy on breast cancer risk and progression to better understand the physiological effects on breast tumor development. She continues her research breast cancer with Dr. Sylvia Plevritis to investigate the impact of mammography screening and treatment on breast cancer incidence and survival. Dr. Geneser received her PhD in computer science from the University of Utah in 2008.

Pejman Ghanouni, MD, PhD, joined the NCI program on July 1, 2010 after completing the Stanford Radiology residency program. Pejman has a very keen interest in research and as an NCI fellow is studying clinical and preclinical applications of MR-guided focused ultrasound surgery. Dr. Ghanouni is a co-Principal Investigator on two human clinical trials using focused ultrasound to palliate painful bone metastases. In January, 2012, Dr. Ghanouni will join the Stanford Radiology Department as an Assistant Professor.

Catherine Moran, PhD, joined the NCI program in April 2011. Her primary research interest is improving lesion characterization in breast MRI through the use of novel contrast mechanisms, with specific application of these techniques in women at a high risk for breast cancer. Training with Dr. Daniel and Dr. Hargreaves, her work encompasses both basic science and clinical translational aspects of breast MRI. Dr. Moran received her PhD in medical physics from the University of Wisconsin in 2009.

Bhayva Shah, MD, began his two year traineeship on August 1, 2011. Dr. Shah will be working with Dr. Sandip Biswal in the Department of Radiology Musculoskeletal Section. He has been busy studying for his Radiology Boards which he will take in September. After completion of his boards, Dr. Shah will decide on an initial research project. In addition to studying, Dr. Shah has been attending the weekly RSL meetings and the residents’ AM and Noon conferences.

T32 Program Graduates

NCI Fellow	Completed	Current Position	Current Institution	Primary Mentor
John Strang, MD	1995	Assistant Professor	University of Rochester, Rochester, NY	Herfkens
Ian Chen, MD	1996	Radiologist	Southwest Washington Medical Center, Vancouver, WA	Li
Susan Lemieux, PhD	1996	Assistant Professor	Diagnostic Imaging Western Virginia Univ., Morgantown, WV	Glover
Bruce Daniel, MD	1997	Associate Professor	Radiology, Stanford University, Stanford, CA	Herfkens
Garry Gold, MD	1997	Associate Professor	Radiology, Stanford University, Stanford, CA	Macovski
Yi-Fen Yen, PhD	1997	Research Scientist	GE Advanced Health Care	Glover
Esther Yuh, PhD	1998	Clinical Fellow	Radiology (Neuroradiology), UCSF, CA	Li & Napel
Roger Shifrin, MD	1998	Assistant Professor	University of Florida, FL	Pelc & Herfkens
Steven Heiss, MD	1999	Radiologist	Radiology Imaging Associates, Denver, CO	Li
Martin Blum, MD	2000	Researcher	PET/Nuclear Medicine, Palo Alto VA, CA	Jeffrey
Curtis Coulam, MD	2001	Radiologist	Gem State Radiology Group, Boise, ID	Sommer
Lawrence Chow, MD	2002	Assistant Professor	University of Oregon, Eugene, OR	Sommer
Samira Guccione, PhD	2002	Assistant Professor	Radiology, Stanford University, Stanford, CA	Bednarski
Yishan Yang, PhD	2002	Research Associate	Radiology, Stanford University, Stanford, CA	Bednarski
Charles Liu, MD	2003	Radiologist	La Jolla Radiology, La Jolla, CA	Herfkens & Sommer
Karl Vigen, PhD	2003	Research Scientist	University of Wisconsin-Madison, Madison, WI	Butts Pauly
Susan Hobbs, MD, PhD	2003	Radiologist	CT Section Chief, Kaiser Permanente, Walnut Creek, CA	Bednarski
John Levin, MD	2004	Radiologist	St. Luke’s Medical Center & Clinic, Minneapolis, MN	Herfkens & Sommer
Laura Pisani, PhD	2004	Postdoctoral Fellow	Radiology, Stanford University, Stanford, CA	Glover
Daniel Margolis, MD	2005	Assistant Professor	Dept. of Radiology, UCLA, Los Angeles, CA	Jeffrey
Daniel Ennis, PhD	2006	Postdoctoral Fellow	University of Washington, Seattle, WA	Pelc
Anthony Faranesh, PhD	2007	Research Scientist	NIH, Washington, DC	Pelc & Hargreaves
Lewis Shin, MD	2007	Assistant Professor	Radiology, Stanford University, Stanford, CA	Herfkens
Michael McDonald, PhD	2007	Research Scientist	NIH, Washington, DC	Guccione
Byard Edwards, MD, PhD	2008	Scientific Researcher	Vanderbilt University	Jeffrey
Cristina Zavaleta, PhD	2008	Scientific Researcher	MIPS, Radiology, Stanford University, Stanford, CA	Gambhir
Jinha Park, MD, PhD	2008	Assistant Professor	University of Southern California, Los Angeles, CA	Gambhir
Stephanie Bailey, PhD	2009	Scientific Researcher	Comprehensive SDSU/UCSD Cancer Center	Plevritis
Moses Darpolor, PhD	2010	Postdoctoral Fellow	Radiation Oncology, Stanford University, Stanford, CA	Spielman
Rachel Bitton, PhD	2010	Postdoctoral Fellow	RSL, Stanford University, Stanford, CA	Butts-Pauly
Grace Tye, MD	2011	Radiologist	Alvarado Breast Center, La Jolla, CA	Jeffrey, Napel

NIH/NCI R25 CA 118681
Stanford Molecular Imaging Scholars - SMIS R25

PI: Sanjiv Sam Gambhir, MD, PhD
Program Manager: Sofia Gonzales, MS

The Stanford Molecular Imaging Scholars (SMIS) program is a cross-disciplinary post-doctoral training program at Stanford University that brings together 45 faculty mentors from 15 departments in the Schools of Medicine, Engineering, and Humanities and Sciences. Faculty mentors provide a diverse training environment spanning biology, physics, mathematics/biocomputation/biomedical informatics, engineering, chemistry, biochemistry, cancer biology, immunology, and medical sciences. The centerpiece of the SMIS program is the opportunity for trainees (PhD or MD with an emphasis on PhD) to conduct innovative molecular imaging research that is co-mentored by faculty in complementary disciplines. SMIS trainees also engage in specialized coursework, seminars, national conferences, clinical rounds, ethics training, and the responsible conduct of research. The three-year program culminates with the preparation and review of a mock grant in support of trainee transition to an independent career in cancer molecular imaging with the ultimate goal of training them to become leaders in the field. Thus far, 16 trainees have entered the SMIS program and 8 have completed the program.

We have just received notification that our program, submitted for a competing renewal in 2010, will be funded for an additional five years (to 2016).

SMIS R25 Program Graduates

SMIS Fellow	Completed	Current Position	Institution	Primary Mentor
Ted Chu, PhD	2008	Research Scientist	Regeneron	Kuo
Jill Lin, PhD	2009	Consultant	Beghou Consulting,	Paik
Keith Hartman, PhD	2009	Senior Analyst	Boston Consulting Group	Gambhir
Bryan Smith, PhD	2010	Postdoctoral Scholar	Stanford University (MIPS)	Gambhir
Henry Haeberle, PhD	2010	Senior Scientific Officer	University of New South Wales, Australia	Contag
Hua Fan-Minogue, MD, PhD	2010	Graduate Student, BMI Program	Stanford University	Gambhir
Jennifer Prescher, PhD	2010	Assistant Professor of Chemistry	University of California, Irvine	Contag
Richard Kimura, PhD	2010	Senior Research Scientist	Canary Center at Stanford for Cancer Early Detection	Cochran

Current SMIS R25 Trainee Research Interests

Rehan Ali, PhD, joined the SMIS program in 2010 under the joint supervision of Drs. Edward Graves and Ramasamy Paulmurugan, after completing his PhD in biomedical image analysis at the University of Oxford. His research focus is the development of non-invasive in vivo techniques for detecting and predicting tumor resistance to radiation therapy, using a combination of experimental and modeling techniques.

Prachi Pandit, PhD, began her SMIS fellowship in 2010 after completing her PhD in Biomedical Engineering at Duke University. Her primary mentor in the program is Dr. Brian Rutt. Prachi, in collaboration with Dr. Jianghong Rao’s group, is working on developing magnetic resonance imaging based molecular imaging systems to image cancer-specific enzymatic activity of protease in vivo. This work focuses on “smart” Gd-based probes, which upon encountering a specific molecular target aggregate to form nanoparticles, thereby increasing the detection sensitivity of the system.

Nicholas Conley, PhD, joined the SMIS program in 2009 after completing his PhD in Chemistry at Stanford. He is working with Drs. Matthew Scott and Jennifer Cochran on projects related to the Hedgehog signaling pathway. Hedgehog (Hh) signaling is responsible for controlling cell fates in most developing tissues and organs, as well as during many regeneration events. Unregulated activation of the Hh signaling pathway leads to birth defects and cancer.

Eric Gonzalez, PhD, began his SMIS fellowship in 2009 after completing a PhD in Physics at Texas Christian University in Fort Worth, Texas. His research interests include the development of algorithms for Positron Emission Tomography (PET). He works with Dr. Craig Levin as his primary mentor to develop a methodology of detecting and processing multiple-photon events that are typically discarded in standard PET imaging.

Jesse Jokerst, PhD, joined the SMIS program in 2009 after completing his PhD in chemistry at University of Texas, Austin. With a background in graduate school that emphasized Raman fluorescent nanoparticles for biomarker measurement in vitro, Dr. Jokerst has found the SMIS program an opportunity to expand his experience in nanotechnology a perfect fit. His primary mentor in the program is Dr. Sam Gambhir.

Benjamin Cosgrove, PhD, joined the SMIS program in 2008 after completing a PhD in bioengineering at MIT. He is working with Dr. Helen Blau to develop molecular imaging approaches, primarily using bioluminescence imaging, to evaluate muscle stem cell behaviors following transplantation. He is testing muscle stem cell therapies by ex vivo perturbation of signaling pathways dysregulated in muscle diseases and validation by transplantation of treated stem-cell populations.

Sharon Hori, PhD, joined the SMIS program 2008. She is integrating mathematical modeling and in vivo experimental techniques to identify ways of accelerating early cancer detection, based on the use of cancer blood biomarker assays to predict tumor volume. Dr. Hori has developed a novel mathematical model relating cancer biomarker secretion kinetics and tumor growth, which is currently being used to identify key factors and processes involved in cancer biomarker secretion and detectability. To test these mathematical predictions, she is also establishing a novel mouse model which links blood biomarker detection and in vivo tumor imaging. She is working with Drs. Sam Gambhir and Ramasamy Paulmurugan.

Marybeth Psyz, PhD, joined Dr. Juergen Willmann’s lab in October 2008. She is interested in multi-modality imaging of pancreatic cancer and identifying new molecular targets for early detection using molecular ultrasound and/or PET-CT imaging. She also investigates other methods for sensitive quantitation of vascular map profiles of microbubble contrast agent signals with real-time ultrasound imaging in mice using a clinical ultrasound scanner and a high-resolution ultrasound scanner for small animals. Mentors for Dr. Psyz include Drs. Juergen Willmann and Sam Gambhir.

NIH/NCI P50 CA 114747

In Vivo Cellular and Molecular Imaging Center at Stanford - ICMIC P50

PI: Sanjiv Sam Gambhir, MD, PhD
Program Manager: Billie Robles, BS

Current ICMIC P50 Postdoctoral Trainee Research Interests

Dominique van de Sompel, PhD, joined the ICMIC program in 2010. Dr. Van de Sompel completed his PhD training at the University of Oxford in Medical Image Processing prior to coming to Stanford and joining Dr. Sam Gambhir’s research lab in multimodality molecular imaging. Dr. Van de Sompel is particularly interested in algorithm development for quantitative in vivo cancer imaging, and would like to learn more about the underlying molecular biology that prompts the need for research in the first place. His current work is focused on Raman spectroscopy and photoacoustic tomography.

Thillai Sekar Veerapazham, PhD, also joined the ICMIC program in 2010. His interests in nanoscale synthesis and assembly for biomedical applications make him a good fit for the labs of Dr. Jianghong Rao and Dr. Heike Daldrup-Link. Dr. Veerapazham will acquire hands-on experience with cell cultures, collecting image data, small animal handling, as well as strengthening his organic and nanoparticle synthetic skills, as well as gaining experience with clinical work. His clinical interests focus on applying his basic science knowledge and experience in areas of breast cancer research.

Yang Liu, PhD, very recently joined the ICMIC program as a postdoctoral trainee in Dr. Zhen Cheng’s lab, the Cancer Molecular Imaging Chemistry Laboratory (CMICL). Dr. Yang received his PhD at the Zhejiang University in Hangzhou, China (2009), where he focused on fluorescent probe development as a graduate student and a postdoctoral fellow. Dr. Yang will continue to explore his interests and apply his expertise in probe development as a postdoctoral trainee in the ICMIC program. His interests in novel probe development for non-invasive detection of cancer are a perfect fit for the ICMIC and the Cheng lab.

ICMIC P50 GRADUATES (NCI P50CA114747)

The following table lists all graduates from our NIH/NCI funded ICMIC program (P50CA114747):

ICMIC Fellow	Completed	Current Position	Institution	Primary Mentor
Sheen-Woo Lee, MD	2005	Assistant Professor	Gachon University Medical School, Incheon, Korea	Biswal
Gayatri Gowrishankar, PhD	2006	Research Scientist	Stanford University	Rao
Ehran Yenilmez, PhD	2007	Research Scientist	Nanomix, Inc.	Melosh
Meike Schipper,MD	2007	Chief Resident, Nuclear Medicine	Stanford University	Gambhir
Weibo Cai, PhD	2007	Assistant Professor	Univ of Wisconsin, Madison, WI.	Chen
Arne Vandenbroucke, PhD	2008	Research Scientist	Cenix BioScience	Levin
Frank Cochran, PhD	2008	Postdoctoral Fellow	Bioengineering, Stanford Univ	Cochran
Michael Helms, PhD	2008	Research Scientist	Cenix BioScience	Contag
Phuoc Tran, MD, PhD	2008	Assistant Professor	Johns Hopkins	Felsher
Zibo Li, PhD	2008	Assistant Professor	Univ of Southern California	Chen
Gang Ren, PhD	2009	Research Scientist	Stanford University	Cheng
Michael Benoit, PhD	2009	Research Scientist	Stanford University	Matin

Introducing a new Training Program: NIH NIBIB T32 EB009653-01

Predoctoral Training in Biomedical Imaging at Stanford – T32

PI: Norbert Pelc, ScD
Program Manager: Teresa Newton, BA

This new multidisciplinary pre-doctoral training program at Stanford University in biomedical imaging technology is approaching the end of year 1 during which time we have successfully recruited two trainees as proposed. Our mission is to train the next generation of researchers in and inventors of biomedical imaging technology. Imaging technology continues to evolve at a rapid pace generating new techniques in research today that will become the standard of care for tomorrow. There is a high need for trained researchers in this field to fill positions in academia, industry, and government. Stanford University has a unique multidisciplinary research effort in biomedical imaging, spanning magnetic resonance, computed tomography and radiography, radionuclide and optical methods for molecular imaging, ultrasound, and hybrid imaging such as Xray/ MR and PET/MR, as well as image processing and analysis for diagnosis, radiation therapy, and science.

Our program attracts students from six different degree granting programs to train in biomedical imaging technology with faculty from 8 different departments and Interdepartmental Programs. In keeping with the program goals to recruit two trainees during our first, planning and recruiting year, we are pleased to introduce two outstanding trainees who have joined our program. Michael Marx is an Electrical Engineering graduate student at Stanford and completed his undergraduate training in electrical and mechanical engineering at Penn State University. Juan Plata is a Bioengineering student who completed his undergraduate training at University of Nevada, Las Vegas, Nevada. We are pleased to welcome these two outstanding students to our training program.

Lucas Center MR Systems Training and Support

Anne Marie Sawyer, BS, RT (R)(MR), FSMRT

MRI Safety Training and System Operation Instruction 2010 - 2011

MRI safety training and system instruction have been provided to 285 new researchers including scientists and clinicians conducting experimental MRI studies at the Lucas Center over the

last twelve months (Figure 1). Initial MRI safety training and the annual refresher course are required for all researchers assisting or conducting studies on any of the MRI systems at the Lucas Center. The annual MRI safety refresher course is required as an on-line tutorial and will provide renewal instruction to 296 researchers (Figure 2). This ensures that all users and assistants are qualified to operate the MRI systems and satisfies Lucas Center and University requirements for safety. MRI system and safety support

is provided to the researchers 7 days a week, 24 hours a day to ensure that research endeavors are successful, generate valuable data, and, above all, are safe for the researchers, the human subjects and the MRI systems and components. MRI safety is an on-going concern as the MRI environment can be a potentially lethal setting without continuing education and persevering support.

The research environment generates many new yet prototype designs in RF imaging coils, imaging accessories, monitoring and response devices such as button boxes, eye trackers, and electroencephalogram (EEG) recorders (Figure 3), and sensory devices. Evaluation of these new devices is on-going to ensure that neither the image data, the safety of the human subject, nor the integrity of the MRI systems are compromised by the presence of these devices in the magnet room, in the bore of the magnet, or in the presence of an RF coil.

Figure 1. Magnet Manager Annemarie Sawyer assists researcher Ryan Kelley from Department of Psychiatry (Allan Reiss, M.D.), Stanford University School of Medicine, with scan subject preparation.

Figure 3. A scan subject is being prepared for a functional MRI scan (fMRI) that includes the MR safe EEG (electroencephalography) system (www.egi.com). Functional MRI is a type of specialized MRI scan used to measure the hemodynamic response (change in blood flow) related to neural activity in the brain or spinal cord. EEG is the recording of electrical activity along the scalp. EEG measures voltage fluctuations resulting from ionic current flows within the neurons of the brain.

Advanced X-Ray and CT Techniques

Inverse Geometry CT and Conventional CT

Our research is directed toward the development of technology and applications of computed tomography (CT). The long-term aim of this work is to push the limits of CT performance, to improve dose efficiency, and to aid in the development of new applications. Intrinsic in these goals is the need to understand the basic limitations in current systems and, when physically possible, to develop solutions to effectively address them.

For many years, we have been working on a project to develop a system that can image an arbitrarily thick section of anatomy (e.g. an entire organ) in a single fast rotation while producing uncompromised image quality and outstanding dose efficiency using an inverted geometry (therefore the term Inverse Geometry CT). In collaboration with GE Global Research, we completed assembly of the first-ever gantry mounted IGCT system and Jongduk Baek reconstructed initial images using an array of 8 sources. The initial images are excellent. We are now completing expansion of the source to 32 elements and expect to test this system in the coming months. One of the limitations of the current system is mechanical complexity. To address this Scott Hsieh is working on concepts for stationary source array systems.

We are also working on a number of problems relevant to all CT configurations. Charles Feng is extending the previous work of Adam Wang, developing an interactive tool for synthetic CT that will allow radiologists to optimize clinical protocols and also allow the creation of realistic images expected from systems that don't yet exist (Feng abstract). One of the challenges of volumetric CT systems is how to measure the spatial resolution (Modulation Transfer Function). Jongduk Baek found that the method described in the literature can be misleading and developed a new technique (Baek

Yuan Yao, Scott Hsieh, Adam Wang, me, Charles Feng, and Jongduk Baek

*Uncompromised image quality
and Dose efficiency*

to improve CT performance is photon-counting detectors. Instead of the currently used technology which measures the total energy of all the x-ray photons that strike the detector in a particular small time period, photon counting detectors sense and process individual photons. However, their response is imperfect and it is important to understand the level of performance that is needed. Adam Wang

studied the impact of different types of performance limitations of these detectors and showed that further improvements are needed before system benefits would be obtained (Wang abstract). One particular challenge for photon counting detectors is handling high count rates. When the intensity is too high the detectors miscount photons and make errors in measuring their energy. Scott Hsieh developed an idea for a dynamic bowtie filter that can, among other things, protect the detector from seeing exceedingly high intensities. The dynamic bowtie can lead to performance improvement additional to those through photon counting detectors (Hsieh abstract).

Sam Mazin, a postdoctoral fellow, left this year to pursue his entrepreneurial dream. We wish him well.

Norbert Pelc, ScD

abstract). Dual energy CT imaging offers important tissue information by measuring x-ray transmission with two x-ray spectra. One system achieves this by rapidly modulating the x-ray tube voltage. We know that, in the ideal world, each of the resulting spectra would be modified by an optimized filter. However, it is not possible currently to have mechanical filters that switch as fast as the tube voltage. Yuan Yao studied the possibility of using a single fixed filter in these rapid kVp-switching systems. We found that gadolinium can lead to noise performance comparable to that of the commercial systems with significant reductions in dose. One technology with significant potential

Advanced X-Ray and CT Techniques

X-Ray Guidance of Interventional Procedures

Our group conducts research with the broad goal of improving the x-ray guidance of minimally invasive procedures, including guidance of radiation therapy. The Axiom Lab houses a clinical C-arm fluoroscopy system, which can also be used for high-resolution, high-contrast CT imaging. This lab is scheduled to be renovated including an upgrade to the new, state-of-the-art, robotic system (Siemens zeego®), which was purchased with American Recovery and Reinvestment Act (ARRA) funding through an NIH Shared Instrumentation Program. The renovation installation is scheduled to begin in the fall of 2012. The current C-arm CT system (Siemens Artis dTA) has been used for a number of in vivo investigations. The Advanced X-Ray Imaging Lab is used for hardware and software development (table-top digital x-ray imaging, cone beam CT, new detector development and X-ray/MR system development).

Software investigations have the primary goal of improving the image quality of C-arm CT reconstructions. Our flexible, open-source JAVA-based framework for C-arm CT reconstruction, including CUDA-accelerated forward and back-projection, has been used to simulate patient motion while acquiring images in a weight-bearing geometry (abstract by Choi, collaboration with University of Erlangen-Nurnberg and Dept. of Mechanical

optimization of an MR-compatible rotating anode x-ray tube continues (abstracts by Lillaney and Shin, NIH R01 X-ray Tube and ARRA supplement), as do our simulations of new designs for an MR-compatible linear accelerator (abstract by Constantin, NIH NCI fellow). The Stanford-Varian collaboration (NIH NCI R01 kV-MV Imaging) continues, with work on detector crystal design optimization using Monte Carlo simulation (abstract by Constantin) and on combined kV and MV reconstruction algorithms (abstract by Keil). This project has the overall goal of removing artifacts due to high-density materials such as fillings and hip implants in radiation therapy treatment planning.

Rebecca Fahrig, PhD

Engineering at Stanford). The weight-bearing imaging project recently received seed funding from the Center for Biomedical Imaging at Stanford (CBIS).

Clinical imaging protocols developed in the Axiom lab include a new investigation into early biomarkers of pancreatitis (abstract by K. Blum), liver blood volume and liver perfusion imaging (abstract by Ganguly, collaboration with University of Erlangen-Nurnberg) and imaging of fresh and chronic myocardial infarct using ECG-gated C-arm CT (abstract by Girard, NIH ARRA R01 Cardiac C-arm CT). All three projects were also in collaboration with Siemens AX.

In hardware developments, design and optimization of an MR-compatible rotating anode x-ray tube continues (abstracts by Lillaney and Shin, NIH R01 X-ray Tube and ARRA supplement), as do our simulations of new designs for an MR-compatible linear accelerator (abstract by Constantin, NIH NCI fellow). The Stanford-Varian collaboration (NIH NCI R01 kV-MV Imaging) continues, with work on detector crystal design optimization using Monte Carlo simulation (abstract by Constantin) and on combined kV and

Research Group Updates

Image Analysis, Bioinformatics, and Computational Modeling

Laboratory of Imaging Informatics (LII)

Our research group uses computational methods to leverage detailed information about disease that is depicted in images (“imaging phenotypes”) to enable biomedical discovery and to guide physicians in providing personalized care. Our work spans a broad gamut, from basic science discovery (using image phenotypes to define molecular characteristics of diseases) to clinical practice through translational research (decision support, disease profiling, treatment response assessment, and personalized treatment selection).

Basic science activities: Just as biology has been revolutionized by online genetic data, our goal is to advance radiology by developing computational methods to extract quantitative and semantic content from images (“image biomarkers”) and to use them in conjunction with clinical, pathology, and molecular data to discover image-based predictors of disease and treatment response. Our ultimate goal is to “profile” patients based on image-based characteristics to enable personalized care and to detect whether disease is responding to treatment earlier than currently possible. Our laboratory is one of the sites in the National Cancer Institute’s Quantitative Imaging Network (QIN), a national research consortium which is advancing the science of quantitative methods of imaging to understand cancer and improve its treatment. We are developing a national informatics infrastructure to define a new paradigm for acquiring, mining, and using a broad range of quantitative imaging data in cancer research, and to provide decision support to physicians based on quantitative imaging assessments of patients with cancer. We are also developing innovative imaging informatics methods to enable this work, including (1) tools to efficiently and thoroughly capture the semantic terms radiologists use to describe lesions; (2) standardized

top row from left: Francisco Gimenez, Hakan Bulu, Lior Weizman, Rohan Bansal, bottom row from left: Hayit Greenspan, Alan Snyder, Jiajing Xu, Daniel Rubin, Vanessa Sochat, Pooja Naik. Missing: Jessica Faruque, Debra Willrett, Tiffany Ting Liu, Mustafa Safdari, Raghav Pasari, Kelly Englese

Personalized medicine through Computational methods

terminologies and ontologies to enable radiologists to describe lesions comprehensively and consistently; (3) novel image processing methods to extract quantitative features from images that are informative of the underlying biology of lesions; and (4) a large database of annotated quantitative imaging cancer studies as a resource for discovering new biomarkers that will improve the sensitivity of detecting cancer treatment response.

Translational and clinical activities: We are developing and translating our biomedical informatics methods into clinical workflow to improve radiology practice. Projects include (1) content-based image retrieval to improve radiologist diagnostic accuracy; (2) automated segmentation of lesions in serial imaging studies, enabling physicians to objectively and reproducibly assess lesions in images and to monitor the response to treatment; (3) quantitative image analysis of retinal images to detect and monitor progression of eye diseases, (4) natural language techniques to enable uniform indexing, searching, and retrieval of radiology information resources such as radiology reports; and (5) decision support applications integrated into the reporting workflow to improve diagnosis and reporting clarity and completeness.

We collaborate with a variety of investigators at Stanford, in Radiology, Oncology, and Ophthalmology, as well as with investigators outside Stanford. We also participate in a national working group that is developing imaging informatics infrastructure for the cancer Biomedical Informatics Grid program at NCI. Our ultimate goal is to bring cutting-edge radiological knowledge into practice and to guide care of individual patients based on the most robust evidence acquired from imaging.

Research Group Updates

Image Analysis, Bioinformatics, and Computational Modeling

Cancer Systems Laboratory (CSL)

Cancer Systems Laboratory (CSL) views cancer as a complex system whose components can be reverse-engineered for the purposes of understanding the underlying mechanisms of cancer progression and identifying approaches for more effective cancer control strategies. Currently, our laboratory infers complex features of cancer progression through a variety of approaches that include: (1) reconstructing molecular networks of cancer, (2) integrating a diversity of molecular, pathological, imaging and clinical cancer data, and (3) mathematically modeling the progression of primary disease to metastatic stages in patients. Ultimately, our goal is to develop a comprehensive, multiscale view of cancer progression that merges these various approaches.

(1) Reconstructing molecular networks: We apply a wide range of computational and statistical techniques to infer molecular networks underlying cancer using genomic, transcriptomic and proteomic data. These networks often represent interactions between genes or sets of genes, mediated by a diversity of molecular regulators. We use these networks to generate new hypotheses about cancer initiation and progression. Recently, we have been funded by the NCI Integrative Cancer Biology Program as a national Center for Cancer Systems Biology to promote this research with a grant entitled “Modeling the Role of Differentiation in Cancer Progression,” which focus on hematologic malignancies with a multi-disciplinary team across the Stanford campus. We have established a “wet-lab” in LUCAS P169 to experimentally validate our computationally-derived findings. With this new experimental laboratory, we are now expanding our molecular-network-based research to the analysis of solid tumors, specifically the microenvironment of breast cancer.

Molecular networks, Data integration, Mathematical modeling

to identify prognostic significance image biomarkers by leveraging on a vast amount of clinically annotated, publically available lung cancer gene expression microarray. This effort is being supported by pilot funds from GE Medical Systems.

(3) Mathematically modeling clinical cancer progression and cancer control health policies: We develop multi-scale models of the natural history of cancer that describe the stochastic behavior of tumor growth and metastatic spread. We have used these models to address important health policy questions related to early detection, such as: how do screening mammography and MRI impact breast cancer mortality; and how would CT screening for lung cancer impact lung cancer mortality rates? This effort has been funded for over 10 years and has been renewed for an additional 5 years of funding through the NCI Cancer Intervention and Surveillance Network (CISNET).

In summary, CSL brings together computational and biomathematical modelers, engineers, biological experimentalists and clinical researchers to ensure the biological and clinical relevance and translation of our work.

Sylvia K. Plevritis, PhD

(2) Integrating a diversity of molecular, imaging and clinical data: We have embarked on numerous projects that involve the integration of multi-platform cancer datasets through probabilistic modeling. In a recent collaborative effort through ISIS, with investigators from the Stanford Departments of Radiology and Surgery, we are creating an association map between CT and PET image features and gene expression microarrays of human non-small cell lung carcinoma. This map provides a molecular characterization of imaging features of lung cancer. It also enables us

Research Group Updates

Image Analysis, Bioinformatics, and Computational Modeling

Imaging Bioinformatics Laboratory

Our group is primarily interested in how biological information is extracted and quantified from both anatomic and molecular imaging, how it is represented, how it is modeled and how it is disseminated with an outlook toward combining imaging-derived information with other sources of biological and clinical information. We are particularly interested in applying computational techniques toward a better understanding of cancer. While most computational models and analyses focus on a single source or modality of data, it is becoming increasingly clear that models must integrate across a wide variety of data types as well as spatial and temporal scales. Our focus is on developing these types of models.

In the area of molecular imaging, we are working on a variety of projects to improve and standardize the quantitation derived from molecular imaging. While this type of imaging is producing breakthrough biological results, better quantitation and mathematical models will lead to a more detailed understanding of specific biological mechanisms. Examples include statistical analysis of ROI methods, knowledge representations of quantitative imaging, and improving

par with that of genomic and proteomic profiling technologies so that these very different types of information may be treated as siblings computationally. Our philosophy is that for an integrative approach to imaging and non-imaging information to come to fruition, a major pre-requisite is to be able to maximally extract and represent information from imaging, with an emphasis on the specificity of molecular imaging.

David Paik, PhD

software for quantitative imaging. In the area of nanomedicine, we are working on computational methods for representing the structure of nanoparticles in order to enable structure-based queries of online nanomedicine resources and algorithms for hyperspectral unmixing. And finally, in the area of clinical imaging, we are working on methods to better understand the perceptual factors that influence diagnostic accuracy.

Our long-term goal is to enable and simplify the problem of information extraction and information flow from medical/molecular imaging to be on

Radiology 3D Visualization and Analysis Laboratory

Our group addresses the field of medical image analysis, focusing on volumetric visualization, structure segmentation, quantitative analysis, computer-aided detection of lesions, and the capture and use of imaging phenotype and integration with other clinical data, including those from high throughput technologies such as gene arrays, for knowledge discovery and decision support.

Advances here have impact in many technical and clinical areas. Examples are: automated visualization and quantitation of vascular image data, virtual colonoscopy, intra-procedural registration of 2D fluoroscopic images

L-R: Sandy Napel, Hayit Greenspan, Alan Snyder, Jiajing Xu, Francisco Gimenez (sitting in front of Jiajing), Jessica Faruque, Inseong Kim

to molecular profiles of excised tissue in lung cancer, evaluation of CAD of lung nodule data, evaluation methods for CAD in the absence of ground truth, and gaze tracking for improving interpretations. We are also starting new projects aimed at prediction of survival and response to therapy in liver and lung cancer as a function of imaging features. Based on our work this past year, 7 new manuscripts have been accepted for publication, 8 presentations were given at international meetings, and 4 grant proposals, all related to our ISIS initiative, were submitted to the NIH.

Sandy Napel, PhD

Brooke Jeffrey Jr., Nishita Kothary, David Paik, Sylvia K. Plevritis, and Daniel L. Rubin) as well as many other Stanford (e.g., Pierre Khuri-Yakub, electrical engineering) and non-Stanford (Justus Roos: University Hospital Zurich, Geoffrey D. Rubin: Duke University) faculty. This year we have focused on automated feature extraction from liver and lung CT images, efficient methods for the creation of a visual similarity standard for content-based image retrieval and decision support, correlation of image features

Research Group Updates

Magnetic Resonance Research

Interventional and Open MRI

Ultrasound energy can be focused to a point deep within the body without damage to overlying tissues. MRI provides a means to target the treatment, monitor the temperature during treatment, and evaluate the tissue after the treatment. This year, led by collaborators Peji Ghanouni and David Hovsepian, we joined a multicenter trial in the palliation of painful bone metastases with MR-guided focused ultrasound. In addition, we continue our development of advanced guidance techniques for focused ultrasound treatment of diseases in the liver, bone, prostate, breast, heart, and brain.

In the liver application, we demonstrated real-time steering of the ultrasound beam under MR-guidance to targets in the liver during free breathing. We also demonstrated that acoustic radiation force MR imaging can provide a picture of the focus for focal spot calibration in a fraction of the energy that a low temperature test spot would require. Our collaborative project with Graham Sommer and Chris Diederich on MR-guided high intensity ultrasound ablation in the prostate with transurethral ultrasound applicators tested our methods for feedback

Pejman Ghanouni, Andrew Holbrook, Urvi Vyas, Viola Rieke, Patrick Ye, Rachelle Bitton (in front of Patrick), Ronnie Instrella, Ron Watkins, Randy King, Juan Plata, Elena Kaye, Hyo-Seon Yoon (in front of Elena), Mike Marx, and Kim Butts Pauly

MR thermometry and demonstrated a significant reduction in temperature errors. We demonstrated methods for MR-guided focusing in the presence of phase aberrations based on acoustic radiation force imaging. In collaboration with Bill Newsome in Neurobiology, we have been investigating neuromodulation with focused ultrasound. See these abstracts on pages 88-91.

Kim Butts Pauly, PhD

and control of the treatment. In addition, we are developing a real-time integrated thermometry/diffusion acquisition for monitoring thermal ablation in the prostate. In our cardiac project, in collaboration with Mike McConnell, our hybrid multibaseline-referenceless cardiac thermometry method has been implemented with real-time spiral imaging. In collaboration with Bruce Daniel, we investigated the visibility and palpability of focused ultrasound lesions in breast tissue.

In the brain, we extended the hybrid multibaseline-referenceless processing to

Functional MR Imaging

The functional MRI group continues to develop and optimize methods for the acquisition of functional MR imaging data. Projects include the development of fMRI methods that reduce signal dropout and/or improve efficiency, real-time biofeedback for training brains and reduction of physiological noise in fMRI signals and investigation of brain network dynamics. In addition, we continue to play an active role in the NCRF-funded FIRST BIRN schizophrenia test bed project, with Gary Glover as the chair of the calibration working group.

The following are only a few of the highlights of scientific progress; see abstracts for further details.

Grad student Catie Chang received her PhD in EE with her thesis focused on dynamic properties of intrinsic brain networks. During her defense presentation, it was noted that Catie has published an astonishing 18 papers during her 5 years, with ten authored by her. She was the

Yuan Yao, Paul Mazaika, Haisam Islam, Kevin Johnson, Qingfei Luo, Catie Chang, Gary Glover. Not shown: Fumiko Hoeft, Allyson Rosen, Elizabeth Stringer.

and theory demonstrate that, amazingly, this signal loss does not lead to loss of fMRI signal. This is very good news for the users of this technology in our group and the Lucas Center.

Gary Glover, PhD

first to discover that the brain's resting state networks are highly variable in their inter-region activity, and her publication on this work has been cited an exceptional 20 times in only the past year. This suggests high scientific acceptance of this exciting finding.

Postdoc Qingfei Luo has found that when a high-density (256 channels) EEG cap is used during concurrent EEG/fMRI experiments, the large mass of wires that exit the head coil under the subject's head cause a large amount of signal dropout. However, his measurements

Research Group Updates

Magnetic Resonance Research

High Field MR

The long-term objective of the high field MR group is to develop a next-generation 7 Tesla whole-body magnetic resonance imaging (MRI) facility at Stanford to serve as a platform for cutting-edge imaging research and development, as well as for radiological and neuroscience research. The scientific scope of the projects that will use this new facility will span the range from fundamental biology to patient-based clinical imaging research. The group approach is interdisciplinary, bringing together researchers from the specialties of physics, engineering, bioengineering, biology, physiology, radiology, neurology, psychiatry, and psychology. The 7T MR facility will act as a catalyst and common platform for this broad group to create, refine, implement, validate and utilize the most advanced forms of magnetic resonance imaging. Major patient-based imaging research applications of the next-generation 7T MRI platform will include studies of brain development, psychopathology, drug dependence, alcohol-induced brain damage and its functional consequences, neurodegenerative processes, brain injury, musculoskeletal disorders, and therapeutic interventions associated with some or all of the above.

Major technology development directions that will be enabled by this

Michael Zeineh, Priti Balchandani, Jonathan Lu, Jason Su, Prachi Pandit, Manoj Sananathan, Mohammad Khaligi, Brian Rutt.

high field MRI to unprecedented levels of spatial resolution, metabolite and iron sensitivity, and tissue characterization. Major users are expected to come from interdisciplinary laboratories directed by international leaders in imaging research. Projects and research foci have already been established in the following areas: high field and high sensitivity MRI methodology development, developmental disorders and clinical neuroscience, DTI methodology development, musculoskeletal and breast MRI methodology development, parallel transmit and RF pulse technology development, psychiatric disorders and neuroimaging, MR spectroscopic imaging methodology development, psychiatric disorders and clinical neuroscience, cognitive neuroscience and neurovascular imaging.

Brian Rutt, PhD

next-generation 7T MRI platform include MR spectroscopic imaging (MRSI) of the proton (1H) nucleus as well as non-proton nuclei in both brain and musculoskeletal systems, advanced perfusion and diffusion tensor imaging in brain, and, importantly, parallel transmit technology for mitigating B1 inhomogeneities that limit the use of high magnetic field MRI in any organ system. The initial goals of the high field MR group are to develop software and hardware methods to allow 7T MRI to have a much greater impact on clinical research than possible before, as well as to extend the capabilities of

Translational Tumor and Stem Cell Imaging lab

Our team develops MR imaging techniques for cancer imaging and stem cell imaging, which can generate detailed information about specific cells in the body. The ultimate goal of our research is to detect specific cells in the tumor environment that are linked to poor prognosis, to monitor tumor cell-targeted therapies, and to monitor stem cell engraftment outcomes in vivo. We utilize iron oxide nanoparticles to specifically target tumor-associated macrophages (TAM), which are associated with tumor progression and an unfavorable prognosis. We investigate novel therapeutics that improve tumor delivery of diagnostic and therapeutic macromolecules and we are developing combined diagnostic and therapeutic (“theranostic”) nanoparticle compounds in this context. We just started a first clinical trial to investigate the value of the nanoparticle-based contrast

agent ferumoxytol for the detection and characterization of bone sarcomas in patients. We also utilize nanoparticle based MR contrast agents to investigate stem cell engraftment outcomes in vivo. We label stem cells with clinically applicable cell markers and investigate the imaging characteristics of successful versus unsuccessful stem cell transplants with MR imaging. We currently focus these investigations on in vivo monitoring of nanoparticle labeled stem cell transplants in osteochondral defects of knee joints for the purpose of cartilage regeneration. We recently added evaluations of novel, activatable, MR contrast

Research Group Updates

Magnetic Resonance Research

Body MR Imaging

The body MR imaging group focuses on applications of MRI including abdominal imaging, musculoskeletal imaging, breast imaging, and cardiovascular imaging. Our collaborators include numerous clinicians at Stanford Hospital as well as scientists at GE Healthcare and Electrical Engineering. More information is at <http://bmr.group.stanford.edu>.

Over the past year, Misung Han received her PhD, specializing in rapid MRI techniques for breast imaging. Manoj Saranathan and Pauline Worters presented extensive work in non-contrast vascular imaging techniques at the Magnetic Resonance Angiography Club annual meeting. Catherine (Kitty) Moran received funding as a NCI fellow in our Department. Caroline Jordan received an honorable mention for her efforts as a TA in BioEngineering

Back L to R: Catherine Moran, Brian Hargreaves, Brady Quist, Kyung Sung, Marcus Alley, Bragi Sveinsson, Haisam Islam, Manoj Saranathan, Anderson Nnewiwe; Front L to R: Uche Monu, Kristin Granlund, Pauline Worters, Emily McWalter, Ernesto Staroswiecki, Caroline Jordan

Bruce Daniel and Shreyas Vasanawala, while our MRI methods for imaging near implants are also being used routinely.

Brian A. Hargreaves, PhD

220, while Kyung Sung was a finalist in the ISMRM poster contest. Brian Hargreaves was invited to present our work on high resolution breast MRI at the NIH Edward Nagy New Investigator Symposium. Finally, our work on imaging near metallic artifacts won awards at the SCBT/MR and ISMRM this year.

New students Bragi Sveinsson, Uche Monu, and Brady Quist have joined our group and are working on 3D diffusion imaging and characterization of metallic implants. Our group continues to support clinical scanning in Breast MRI, vascular imaging and body imaging at Stanford Hospital and Lucille Packard Children’s Hospital in collaboration with

In Vivo Magnetic Resonance Spectroscopy and Multinuclear Imaging

Our multinuclear magnetic resonance spectroscopy (MRS) research investigations continue along three distinct directions. First, research on the technical development of ultrahigh field (7T) proton spectroscopy of the brain continues to focus on the design and evaluation of novel adiabatic RF excitation pulses for addressing the magnetic field inhomogeneities encountered at 7T and the development of new pulse sequences to exploit novel contrast mechanisms. Highlights of this work include an innovative adiabatic B1 shimming algorithm for multiple channel transmit, the design and evaluation of a self-refocused adiabatic pulse for 7T spin echo imaging, a new approach for designing adiabatic RF pulses using the Shinnar-Le Roux algorithm. In addition to multiple publications, two US patents, #7,821,263 and #7,966,053, resulted from this work. Furthermore, based on her high field imaging and spectroscopy research, Dr. Priti Balchandani was awarded an NIH K99/R00 grant entitled “High Resolution Magnetic Resonance Imaging and Spectroscopy of Epilepsy at 7T”. Congratulations to Priti, and best of luck to her as she makes the transition from post-doctoral fellow to faculty! Second, under an ongoing program in the development of volumetric 1H MRSI at 1.5 T and 3.0 T, funded through an NIBIB Bioengineering Partnership grant (EB000822), we have begun a multi-site evaluation of a volumetric echo-planar 1H spectroscopic imaging sequence and associated automated data

Sonal Josan, Lasitha Sendaheera, Dirk Mayer, Meng Gu, Priti Balchandani, Dan Spielman, Jae Mo Park, Kelvin Billingsley

evaluation of prostate cancer, metabolic studies of a rat C6 glioma model, imaging of ethanol metabolism in the rat liver, and novel pulse sequences for optimum detection of in vivo pyruvate metabolism. We are currently applying these techniques to the study of multiple pathologies including liver metabolic disorders, brain tumors, prostate cancer, and alcoholism. This work is funded under NIH grants EB009070 “Dynamic Metabolic Imaging of Hyperpolarized Substrates”, AA018681 “Metabolic Imaging of the Cardioprotective Effects of Alcohol and ALDH2 Activators”, and RR09784 “Center for Advanced Magnetic Resonance Technology at Stanford”, in addition to a new DOD award “In Vivo Imaging of Branched Chain Amino Acid Metabolism in Prostate Cancer”.

Daniel Spielman, PhD

reconstruction software. Third, our efforts in the area of hyperpolarized 13C MRS and MRSI continues to move rapidly forward. Hyperpolarized 13C is a highly promising technology capable of directly probing key metabolic pathways by providing unprecedented increases in signal-to-noise ratio for these in vivo measurements. Over the past year we have successfully developed several novel MRSI protocols and associated metabolic modeling tools including the use of hyperpolarized [1-13C]-lactate to investigate cardiac metabolism, hyperpolarized 13C-labeled α -keto-isocaproate for the

Research Group Updates

Magnetic Resonance Research

Clinical Center for Advanced Neuroimaging (CFAN)

State-of-the-art advances in magnetic resonance imaging (MRI) continue to improve neuroimaging. With advanced neuroimaging MR methods, we now routinely map and measure brain tissue water diffusion rates and direction, the perfusion of blood, and the brain’s ability to develop and maintain functional-structural integrity. To develop and apply our expertise in advanced imaging in a large number of diseases in patients, the Clinical Center For Advanced Neuro Imaging (CFAN) is built upon a large framework of funded NIH grants from the RSL, Lucas Center, and Stanford Stroke Center faculty dedicated to bringing the best MRI techniques into everyday clinical use.

We continue to develop and advance imaging technologies in several key clinical areas including diffusion and perfusion techniques for the imaging of acute stroke and of white matter structure and integrity. The 7 tesla MRI scanner is now routinely used to improve higher-resolution tools at high-field and high-speed MRI, focusing on disease processes in stroke, brain tumors, and cerebrovascular diseases using diffusion MRI (DWI), tissue perfusion mapping (PWI), as well as the new field of mapping the brain connectivity, DTI, and susceptibility-weighted MRI (SWI). CFAN also develops and uses high-resolution diffusion tensors to explore and map hippocampus structure and function in active mental tasking to reveal new key findings in the developing and aging brain function, which can be used to separate short-term from long-term structural changes in the brain. The same high-resolution methods are also used in cholesteatomas, trigeminal nerve palsy, and to assess patients with demyelinating diseases such as MS.

State-of-the-art MR imaging sequences pioneered at the Lucas Center, in particular for stroke imaging, are now used worldwide and provides unlimited opportunities for local and international collaborations. Clinical decisions on treatment and therapy are made from our methods even while the patient is still in the MRI for the initial acute event. With two clinical 3T MRIs now housed at Lucas and six installed in our out-patient facilities, we will further advance our MR imaging tools and sharpen our focus on the critical clinical issues with new experimental and clinical MR methods to predict brain injury; to detect diffuse abnormalities in the brain occult to conventional imaging; to further map how the brain and spine are “wired”; to understand the complex physiological stresses and changes that the brain experiences during ischemia and other pathologic processes; and to extend these tools to to improve therapy monitoring.

Under the CFAN umbrella, Professors Greg Albers, Christine Wijman, Martin Lansberg, and Jean-Marc Olivot of the Stanford Stroke Center conduct work on clinical functional neuroimaging for acute stroke and the field of functional imaging of coma patients. Jean-Marc, stroke neurologist, collaborates with Professors Zaharchuk and Moseley on a clinical evaluation of Xenon-enhanced CT perfusion and MR perfusion for transient ischemic attacks. Jian Zhang is a fourth-year graduate student now graduated and working at the NIH. Jian, Deqiang Qiu,

First Row (Left to Right), Wesley Hun, Ryan Spilker, Greg Zaharchuk, Second Row: Tom Brosnan, Thomas Christen, Mike Moseley, Third Row: Jordan Michael Nechvatal, Deqiang Qiu Bottom Row: Georges Hankov, Shangpeng Feng, Caleb Folkes.

Greg Zaharchuk, PhD, MD Michael Moseley, PhD

and Shangping Feng are involved in 3D volume spiral imaging for diffusion and functional imaging applications in mapping hippocampus and cortical connections in the aging brain and in stroke patients. Jordan Michael Nechvatal (Psychiatry) joins this group to gain an understanding of how short-term memories are converted into long-term cortical pathways.

Many of our highly qualified CFAN members interact daily with Dr. Scott Atlas, head of our clinical neuroradiology section, or with Greg Zaharchuk who is an Associate Professor and also a member of the Neuroradiology Section. Greg is PI on an NIH-funded R01, which quantifies collateral blood flow in cerebrovascular disease; he also heads the Neuro Tiger team, a joint effort with GE Healthcare; and collaborates on several projects with Neurology and Neurosurgery to clinically evaluate CFAN methods in patients with altered CNS blood flow in MS, Moyamoya, TIA, stroke, and cerebral vascular diseases of the aging brain. The CFAN

team also extends its expertise to imaging children from the newborn to the developing adolescent with their unique needs for advanced MRI of the brain. Dr. Zaharchuk’s mentee, Albert Hsiao, received the Young Investigator Award for best paper at this year’s SPR meeting.

Dr. Moseley is a past president and Gold Medal winner of the International Society of Magnetic Resonance in Medicine (ISMRM) and was elected as a Lifetime Member of the Society of Magnetic Resonance Technologists (SMRT). As a leading expert and pioneer of stroke imaging, Dr. Moseley also sits on many NIH study sections and journal editorial boards. This year, Dr. Moseley received a highly competitive S10 award from the NIH through stimulus (ARRA) funds. This award provides a major hardware upgrade for our 7T animal system in the Clark Center, which will expand research capabilities for many investigators and their pre-clinical MR work.

Thomas Christen, Wesley Hun, Ryan Spilker, Georges Hankov, and Greg Zaharchuk have developed a battery of clinical imaging methods mapping brain oxygenation utilization and reserve for patients with compromised vascular systems. This has been tied to the magnetic susceptibility brain mapping work of Shangpeng Feng and Deqiang Qiu. This work is being added to the clinical stroke workup protocol in an effort to predict whether acute stroke therapy can be extended in patients receiving early MRI scans at Stanford and Lucile Packard. New CFAN members include Dr. Helen D’Arceuil and Caleb Folkes, a summer student from Oklahoma.

Elemental to the CFAN team and to the Lucas Center, is Thomas Brosnan, Senior Research Staff, who directs the RSL and Lucas IT infrastructure. Tom adapts the novel MR sequences to the clinics where the imaging data is fed in real time to the RSL servers for rapid processing and feedback to the clinicians. Lanzie Rivera provides the administrative support for us and is an instrumental resource when it comes to institutional review boards, grants management, and financial matters.

Research Group Updates

Magnetic Resonance Research

Bammer Lab

The general research focus of the Bammer lab is to develop novel MRI acquisition and reconstruction methods for clinical neuroimaging. Currently, our research program is primarily concentrated around improving pediatric neuroimaging as well as various studies on the adult side. Our lab also provides support for users of the Lucas Center for Imaging who are interested in all sorts of diffusion imaging.

A major goal in our laboratory is to reduce motion- and distortion-sensitivity of MRI by means of various sophisticated methods, such as stereo-vision and RF tracking in concert with real-time MRI. Motion correction can improve the diagnostic quality of MR images, reduce the number of repeat studies, and the need for sedation/anesthesia.

Another major focus of our lab is the development of high-resolution MRI methods for diffusion-weighted and susceptibility-weighted imaging of the brain and spine, which find utility in the diagnostic work-up of traumatic, oncologic, psychiatric, developmental, or neurovascular abnormalities.

Our lab also continues to develop MR imaging sequences and analysis tools to study vasculature on the macroscopic (angiography) and microscopic (perfusion) level. For example, with our collaborators from the Stanford Stroke Center we have developed software tools that

From left to right: Lanzie Rivera, Roland Bammer, Murat Aksoy, Rafael O’Halloran, Lily, Eric Gibbons, Melvyn Ooi, Heiko Schmiedeskamp, Matus Straka, Anh Tu Van, Aaryani Tipirneni. Not pictured: EunSoo Choi, Daniel Kopeinigg and Samantha Holdsworth

Roland Bammer, PhD

can identify, out of a large number of patients, those who might benefit from advanced stroke therapy.

Thanks mostly to the generous support by the NIH, the Bammer Lab continues to grow. Last fall Melvyn Ooi (Columbia University) joined us as Research Associate working on motion correction. Anh Tu Van (Univ. of Illinois) also joined in the fall as a Postdoctoral Fellow. Also in late 2010, Arryani Tipirneni (St. Jude’s Hospital Memphis) started as Staff Scientist. Lastly, this summer Eric Gibbons (Univ. of Salt Lake City) joined us as a BioE graduate student and has already made fantastic progress.

We had also a couple of promotions this year. Matus Straka was promoted to Senior Research Associate. In addition, both Matus Straka and Samantha Holdsworth have become parents for the second time. Congratulations! Murat Aksoy – our hitstar EE student – graduated and was immediately promoted to Research Associate. Just recently, Didem Aksoy was promoted to Staff Scientist. Congrats to both!

Last fall was also the time when a strong pillar of our lab moved on to new endeavors. Stefan Skare, our long-time RA and friend, went back to Stockholm where he is now junior faculty at the renowned Karolinska hospital.

Musculoskeletal MR Imaging (MMR)

Dr. Gold, who is PI on an NIH-funded R01 for the study of osteoarthritis, an Arthritis Foundation grant, and a multi-investigator industry funded project to develop advanced MR applications, collaborates daily through his research with Lucas Center faculty. Through his research and basic science collaborations, Dr. Gold has been able to introduce a number of new solutions for musculoskeletal imaging into clinical use. These include improved MR imaging around metallic implants, isotropic 3D imaging, and sodium MRI for detection and characterization of osteoarthritis. Dr. Gold’s background and training in Electrical Engineering and as a practicing radiologist makes him an ideal collaborator for faculty, postdocs, graduate students, and undergraduates who are interested in discussing and understand-

ing biomedical imaging limitations and requirements for clinical applications. We have strong collaborative ties with the Departments of Electrical Engineering, Mechanical Engineering, Human Biology, Orthopaedic Surgery, and Bioengineering, contributing to the success and evolution of our primary research goals. We actively seek to further educate and train our research team members through various means including clinical scanning, translational hardware development, abstract and peer-reviewed publications, presentations at major conference venues, and in-house didactics. We believe that a diversely educated and experienced team will translate into further advances in musculoskeletal imaging.

Research Group Updates

Molecular Imaging

Multimodality Molecular Imaging Lab (MMIL)

We are developing imaging assays to monitor fundamental cellular events in living subjects. We are actively investigating technologies such as micro-positron emission tomography (micro-PET); bioluminescence optical imaging with a charge coupled-device (CCD) camera; fluorescence optical imaging; micro-computerized axial tomography (microCAT); ultrasound; photoacoustics; intravital microscopy; and Raman spectroscopy in small animal models. Our goals are to marry fundamental advances in molecular/cell biology with those in biomedical imaging to advance the field of molecular imaging. We have a particular focus on cancer biology. We have developed several reporter genes/reporter probes compatible with all of the above imaging modalities. These reporter genes are being used in cell trafficking models, gene therapy models, as well as in transgenic models for studying cancer biology. We are developing novel nanoparticle for Photoacoustics, Raman, and multimodality imaging strategies. Imaging of biologics with engineered proteins for cancer cell surface targets are being pursued. Assays to interrogate cells for mRNA levels, cell surface antigens, protein-protein interactions, protein phosphorylation, and intramolecular folding are also under active development. We are also extending many of these approaches for human clinical applications. New patient trials for PET imaging of T-cell trafficking in patients are being performed with our reporter gene strategies. We are also developing several new PET agents for cell surface targets based on new protein scaffolds.

Sanjiv Sam Gambhir, MD, PhD

Cancer Molecular Imaging Chemistry Lab (CMICL)

The main research of our group is to develop novel multimodality imaging probes and techniques for cancer early detection. Our multidisciplinary team is composed of members with expertise in organic chemistry, radiochemistry, bionanotechnology, biochemistry, molecular and cell biology, radiological science, medicine, and molecular imaging.

Currently, we are actively studying several important problems in the molecular imaging field. First, we are investigating a variety of novel platform molecules (peptides, proteins, nanoparticles) as universal strategies for cancer imaging. Second, we are establishing new methodologies for site-specific labeling these platform molecules for multimodality imaging. Third, by applying the knowledge obtained from the above research, we are optimizing PET and optical imaging probes for imaging of melanoma, breast cancer, prostate cancer, and ovarian cancer, and we hope to quickly translate two molecular probes into clinical PET imaging in near future.

The research is supported by National Institute of Health, Department of Defense, Melanoma Research Alliance and Radiology Department at Stanford.

Trainee fellowships are supported by China Scholarship Council.

Zhen Cheng, PhD

Research Group Updates

Molecular Imaging

Cellular and Molecular Imaging Lab (CMIL)

The general research interest in the Rao lab is to develop novel molecular probes and imaging strategies for in vivo imaging by combining chemical synthesis and macromolecular engineering with imaging technology. Current projects are broadly defined in the following areas:

1) Multimodality imaging of enzyme activity in vivo: As a unique class of protein molecules, enzymes catalyze biochemical transformations and are widely implicated in biological processes and diseases. We are developing “smart” activatable probes for imaging and detection of beta-lactamase activity from Mycobacterium tuberculosis (TB) in vivo to study TB biology and to evaluate the efficacy of therapeutics in pre-clinical animal models. The second class of enzyme target we are interested in is proteases, many of which display aberrant activity in diseases such as cancers and arthritis. We are employing both small molecule probes and nanoparticles-based nanosensors for in vitro detection and in vivo imaging of the activity of proteases such as matrix metalloproteinases and furin in cancer cells. Toward imag-

ing these enzyme targets, different imaging modalities have been employed including optical imaging, magnetic resonance imaging, and positron emission tomography.

2) Developing general strategies to label proteins and RNAs in living cells: Our approach is to design small organic dye molecules that are not fluorescent initially but that become fluorescent after binding to a receptor or tag fused to either a protein or RNA molecule of interest. We are combining rational design and library selection methods, such as SELEX and phage display, to discover such novel molecular tags for super high-resolution single-molecule imaging in living cells.

3) The third area is nanotechnology: We are applying both protein engineering and nano engineering to cre-

ate novel nanoparticles for imaging and sensing applications. We invented the QD-BRET technology widely applicable for in vitro biosensing and in vivo imaging. We are currently synthesizing novel multiple functional nanoparticles for multi-modality cancer imaging and theranostic applications. One example is fluorescent magnetic nanoparticles with tumor-specific prodrug conjugated for breast cancer imaging and treatment in a collaborative effort with Dr. Heike Daldrop-Link’s lab.

Molecular Imaging Instrumentation Laboratory (MIIL)

Our research interests are to advance instrumentation and algorithms for the non-invasive imaging of basic cellular and molecular signatures associated with disease. These new “cameras” image photon emissions from molecular probes designed to target specific molecular processes associated with disease in cells located deep within the tissues of living subjects. The technical goals of the instrumentation projects are to advance the photon detection efficiency and spatial, spectral, and temporal resolutions. The algorithmic goals are to understand the physical system comprising the subject tissues, photon transport, and camera, and to realize the best available reconstructed image quality and quantitative accuracy. The work involves the design, development, and testing of novel position sensitive photon sensors and systems; low-noise readout electronics; data acquisition electronics; computer modeling; computer graphics; tomographic image reconstruction algorithms; signal/image processing algorithms; and data/image analysis. Key goals of our research are to incorporate these innovations into practical imag-

Craig Levin, PhD

ing devices and introduce new in vivo imaging tools to advance studies of molecular mechanisms and aid discovery of novel treatments of disease in the clinic as well as in preclinical research. If successful, these novel systems will substantially enhance the visualization and quantification of subtle molecular signatures associated with disease with the hope that molecular imaging can play a role in earlier disease management. The research is supported by grants from the National Cancer Institute, National Institute of Biomedical Imaging and Bioengineering, Department of Energy, GE Healthcare and Philips Healthcare. Trainee fellowships are supported by Stanford’s Bio-X Program, School of

Medicine Deans Fellowship Program, Stanford Molecular Imaging Scholars Program, Stanford REU Program, US Department of Defense, Society of Nuclear Medicine, Swedish Research Council, National Science and Engineering Research Council of Canada, China Scholarship Council, AXA Research Fund, and TLI Inc.

Molecular Imaging

Cardiovascular Cellular & Molecular Imaging Laboratory

Ischemic heart disease is the number one cause of morbidity and mortality in the United States. The repeated ischemic insults can lead to congestive heart failure, which is the leading cause of hospital admissions for people aged 65 years and over. In the next decade, cardiovascular diseases will likely be targeted at the basic cellular and molecular levels. The Cardiovascular Cellular & Molecular Imaging lab (<http://wulab.stanford.edu>) combines expertise in molecular and cell biology, cardiovascular physiology, and molecular imaging. We work on the biological mechanisms of adult stem cells, embryonic stem cells, and induced pluripotent stem cells. We use a combination of gene profiling, tissue

research in cellular and gene therapies for ischemic heart disease in the 21st century.

Joseph Wu, MD, PhD

engineering, physiological testing, and molecular imaging technologies to better understand stem cell biology in vitro and in vivo. For adult stem cells, we are interested in monitoring stem cell survival, proliferation, and differentiation. For ESC, we are currently studying their tumorigenicity, immunogenicity, and differentiation. For iPSC, we are working on novel derivation techniques. We also work on development of novel vectors and therapeutic genes for cardiovascular gene therapy applications. The eventual goal is to establish molecular imaging as a platform for translational

Molecular Imaging of Nociception and Inflammation Lab (MINIL)

Chronic pain sufferers are unfortunately limited by poor diagnostic tests and therapies. The lab is interested in using multi-modality molecular imaging techniques to study nociception and neuronal inflammation as a means of improving objective, image-guided diagnosis and treatment of chronic pain generators. Deepak Behera, DNB continues to admirably lead and manage the lab, juggling a number of projects, collaborations and students. This past year has brought some new additions to the lab including MedScholar Eric Davalos, and new collaborations with Garry Gold and Brian Hargreaves (as part of the Tiger Team) to help develop improved isotropic MR approaches for MR Neurography. Another MedScholar, David Attarzadeh, has been studying platelet-rich plasma therapy and whether or not it helps heal tendons. Preeti Borgohain and Supradha Nagineni have also recently joined the lab

role of mesenchymal stem cells and macrophages in the prosthetic-induced osteolysis and in fracture models. A new collaboration with Pankaj Jay Pasricha, MD, Chief of the Division of Gastroenterology has formed in hope of finding better PET-based methods to study abdominal pain syndromes.

Sandip Biswal, MD

and will be studying the role of various neuronal mediators in chronic pain models using PET-MRI. We continue our exciting collaborations with Justin Du Bois, PhD, William Parsons, BS, John Mulcahy, PhD, Frederick Chin, PhD, Aileen Hoehne, PhD, Bin Shen, PhD, and David Yeomans, PhD, studying the role of voltage-gated sodium channels in neuropathic pain using PET-MRI and radiolabeled guanidinium toxins. Important collaborations with the Stuart Goodman Lab continue to thrive as we continue to examine the

Research Group Updates

Molecular Imaging

Cellular Pathway Imaging Laboratory (CPIL)

The current foci of our lab are 1) to develop new molecularly targeted therapy for triple negative breast cancer (TNBC), 2) to study the molecular mechanisms involved in tamoxifen resistance in breast cancer, and 3) to explore the use of non-invasive molecular imaging of histone methylations in living animals. Breast cancer is a highly heterogeneous disease, and there is a growing body of evidence that this heterogeneity occurs at both genetic and phenotypic levels. Although breast cancer research has improved the efficacy of therapies, especially for the treatment of a sub-type of breast cancer that is estrogen receptor positive (endocrine therapy), the increase in the incidence of the receptor negative phenotype and the presence of the receptor positive anti-estrogen non-responsive (tamoxifen resistant) phenotype have contributed to a continual increase in the mortality rates of breast cancer. Two common subtypes of breast cancer, the triple negative phenotype and receptor positive phenotype that develops tamoxifen resistance during treatment, are hard to treat clinically. We mainly target microRNAs, the global regulators of gene expression, which are deregulated in cells under different pathological conditions. Similarly, we study the biological role of ER β -, the second sub-type of ER, whose role in different types of breast cancers has largely been ignored thus far, and which is over-expressed in breast cancers of TNBC phenotypes. Specifically, we are interested in developing a combinatorial therapeutic approach in that we will combine ER β -specific ligands with the down-regulation of some specific microRNAs, which are over-expressed in receptor negative breast cancers. Lastly, we are also interested in developing new in vivo imaging assays to monitor different epigenetic processes, especially histone methylation, which are critical for maintaining cellular homeostasis, and may be potential therapeutic targets for treating many cellular diseases with altered cellular homeostasis, including different cancers.

Ramasamy Paulmurugan, PhD

Translational Molecular Imaging Lab (TML)

In the United States, cancer continues to be the leading cause of death in patients between 25 and 64 years of age, and the second leading cause of death in patients older than 65 and between 1 and 14 years. Prognosis and survival of patients with cancer depends on tumor stage of the cancer at the time of diagnosis, therefore, early cancer detection holds great promise in prolonging survival and improving quality of life in cancer patients. Novel imaging strategies that allow detection of cancer at early, still curable stages are thus highly desirable. With the advent of novel therapeutic options for cancer patients, there is an increasing demand for non-invasive imaging biomarkers to identify those patients early on that benefit most from a given treatment or to terminate or modify treatment for those patients not responding to a certain treatment.

In our Lab, we focus on the development and clinical translation of novel molecular and functional imaging biomarkers. We have a special focus on imaging abdominal and pelvic cancer including pancreatic, liver, renal, ovarian, and prostate cancers. We further advance clinically available radiological imaging modalities such as ultrasound, magnetic resonance imaging (MRI), and positron emission tomography (PET) as promising imaging tools for early detection and treatment monitoring of abdominal and pelvic cancer.

Our mission is to translate these novel molecular and functional imaging strategies into clinical protocols for improved patient care in the shortest possible time frame.

Jürgen K. Willmann, MD

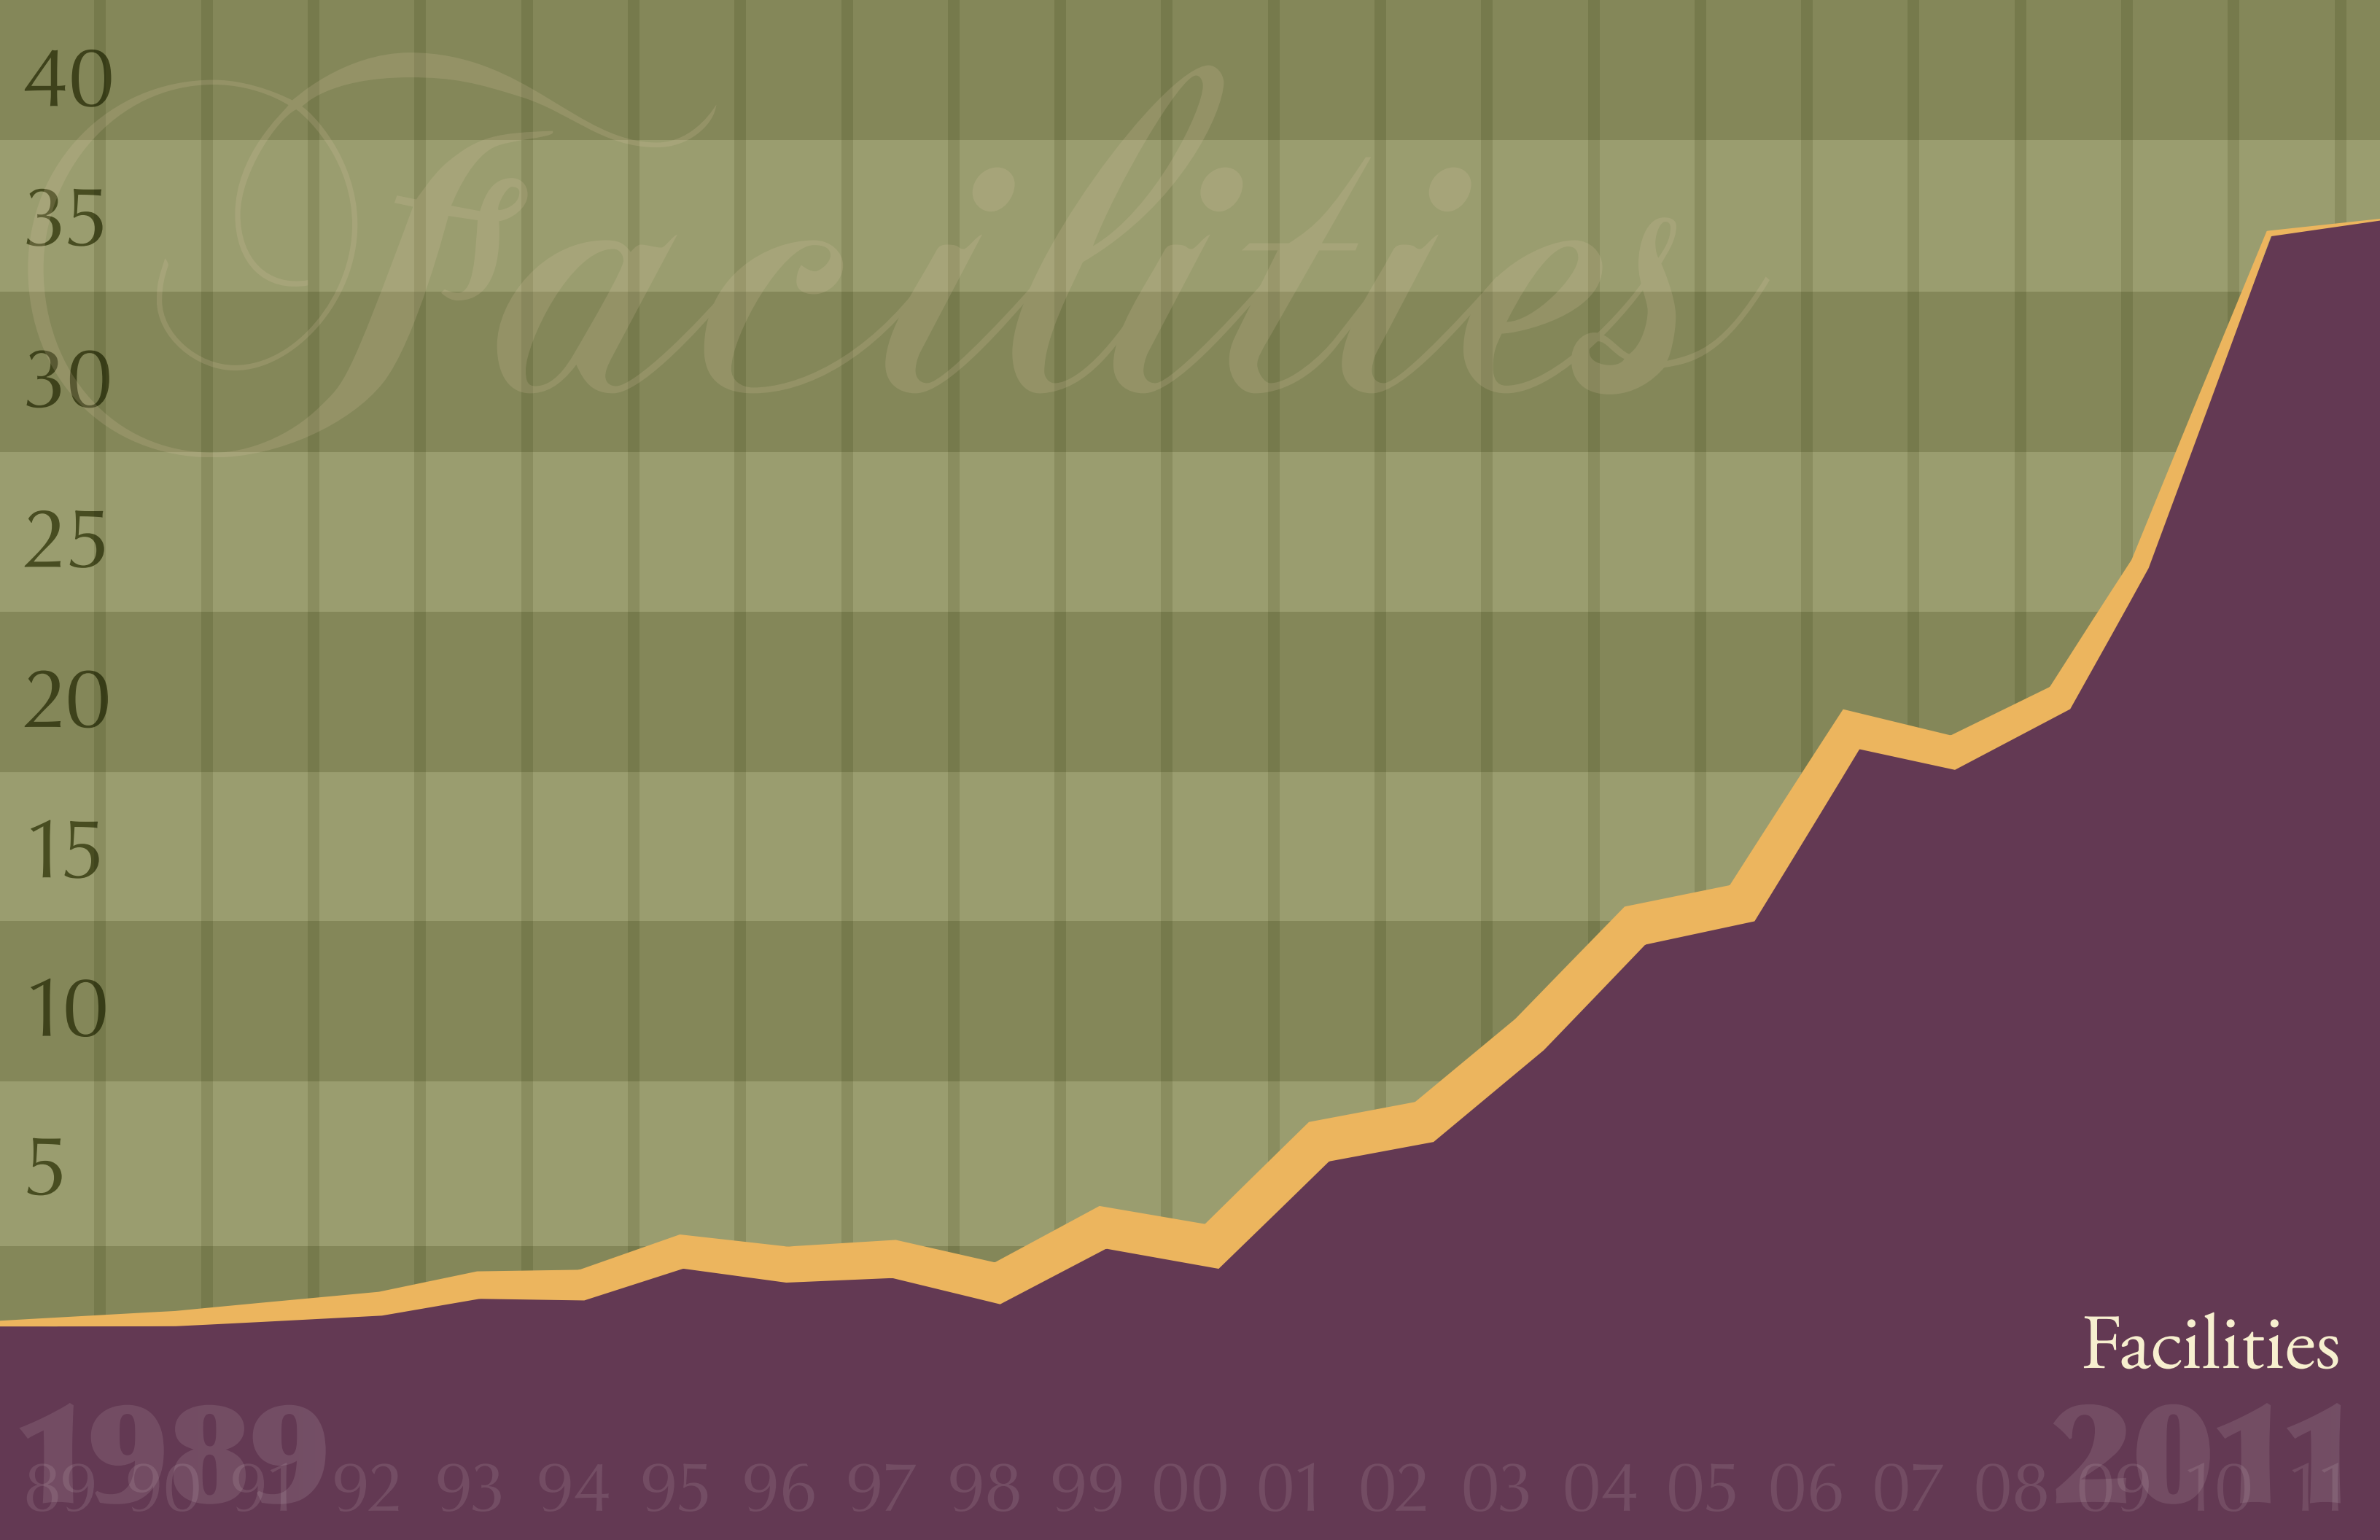

Cancer Molecular Diagnostics Laboratory

Our group is focused on the discovery and validation of blood-based molecular diagnostic markers for cancer early detection. We are interested in defining novel protein signatures for breast and ovarian cancers, including sub-types of these diseases. These protein signatures have potential applications such as molecular indicators of cancer risk, diagnosis, progression, and recurrence. Our primary tools are liquid chromatography and mass spectrometry, which are used to perform in-depth quantitative proteomics, and to characterize post-translational modifications associated with disease state. Using human plasma samples, tumor tissue, cancer cell lines, and genetically engineered mouse models, the origins of these proteins are being investigated. This laboratory is also focused on the identification of proteins with expression restricted to the surface of cancer cells, which can be used as novel targets for molecular imaging technologies. This year has been dedicated to building our lab and establishing collaborations with Stanford investigators and investigators outside Stanford.

Sharon Pitteri and Majlinda Kullolli

Sharon Pitteri, PhD

Stanford Radiology 3D and Quantitative Imaging Laboratory (3DQ Lab)

Sandy Napel, PhD, Lab Director
R. Brooke Jeffrey, Jr., MD, Lab Director
Charles Stanley, RT(R)(CT)(MR), Lab Manager

The Stanford Radiology 3D and Quantitative Imaging Laboratory is guided by the mission of developing and applying innovative techniques for efficient analysis and display of medical imaging data through interdisciplinary collaboration. Since 1996, our clinical goal has been to deliver 3D imaging advances to the Stanford and surrounding communities as rapidly as possible for the swift and accurate diagnosis, tracking, and treatment of disease; our educational goal is to disseminate knowledge to replicate our 3D services at other institutions; we continue to facilitate cutting edge research through our collaborations with faculty in Radiology and other Departments. In early 2011 we changed our name to “Stanford Radiology 3D and Quantitative Imaging Lab (the 3DQ Lab).” This was done to reflect the Lab’s increasing involvement in quantitative imaging, as our resources are being sought out and have expanded our scope beyond the traditional “images as pictures” paradigm.

Progress

Clinical: Over the past year, the 3DQ Laboratory has continued its operations simultaneously in the Lucas Center as well as the James H. Clark Center, a building dedicated to interdisciplinary science. Our average monthly 3DQ volume has held steady at approximately 950 examinations, and we have processed over 89,000 examinations overall since our inception. The majority of our referrals continue to come from vascular surgery, cardiothoracic surgery, gastroenterology, cardiology, urology, reconstructive surgery, orthopedics, neurology, and neurosurgery. 3DQ clinical procedures now offered by the Lab include Volumetric rendering of liver volumes to aid in tumor quantification(fig 1), Volume rendered view of vascular structures to assess stent placement (fig 2), and musculoskeletal exams to aid in surgical planning (fig 3).

Volume rendered view with edge enhancement of post stent placement in the distal aorta and proximal iliac. Renal anatomy is also visualized. Vascular imaging remains the highest clinical volume of work done in the 3DQ lab.

Composite view of liver showing biliary tree (purple), portal veins (teal), hepatic veins (blue), hepatic arteries (red), and large hepatic mass (green). These images and quantification measurements are provided for use in surgical planning techniques and tumor tracking. Volumetric and Quantitative imaging is a fast growing segment of the work done in the 3DQ lab.

Education: This year the 3DQ Laboratory has been attended by international visiting scholars from Japan, China, and Kazakhstan as well as Stanford Radiology fellows, residents, and medical students who acquire skills in 3D processing and interpretation as part of their medical training. Stanford researchers from engineering and medical departments have also been trained in processing and acquiring 3D images and data for research projects, including measurements of craniofacial deformities for reconstructive surgery, pulmonary vasculature volumes for 3D model fluid flow simulations for vascular surgery, and 3D modeling for multimodality small animal imagers.

Research: The research arm of the lab hosts an annual average of 8 graduate students and post-doctoral scholars from several departments of the university, as well as 2 clinical MD researchers. This year, projects included investigations by visiting physicians from Japan of the utility and limitations of cardiac CT angiography, and use of eye gaze-tracking to understand and improve the detection of pulmonary nodules in volumetric CT scans.

Finally, reflective of the envisioned growth in quantitative imaging, Dr. Daniel L. Rubin, MD, MS, has joined the 3DQ Lab to lead our research and translational efforts in this area; we have already begun to offer core lab services for clinical trials that use imaging as surrogate biomarkers.

Infrastructure

The last 12 months have been a time of transition for the Lab as 2 of its pioneers have departed to continue their careers at Duke University. Lab co-Director Dr. Geoffrey D. Rubin left to assume the position of Chairman of Radiology at Duke University, and Lab Manager Laura Pierce left to manage the nascent 3D Lab at Duke. Current Stanford 3DQ Lab personnel include: Charles Stanley, 3DQ Laboratory manager; senior 3DQ technologists

Linda Horst and Marc Sofilos; 3DQ technologists Kristen Bogart, Caryn Damits, Keshni Kumar, Rhea Lang, Nancy Ware, and Shannon Walters. Support staff includes administrative assistants Debra Frank and Lakeesha Winston, and database administrator, Kala Raman.

In the Clark Center, a central area table invites professional collaboration, and student desks with moveable workspaces provide areas for independent research. The Lucas Center 3DQ Laboratory also houses equipment on a central area table, surrounded by student carrels. The lab equipment consists of 12 advanced 3D workstations, two research and development servers for image and data storage, and three TeraRecon servers, which also provide remote 3D rendering to other parts of the Stanford medical community.

On flat panel: Nancy Ware, Marc Sofilos, Lakeesha Winston; Back Row L-R: Shannon Walters, Debra Frank, Linda Horst, Rhea Liang, Kristy Bogart, Keshni Kumar, Caryn Damits, Kala Raman; Front Row L-R: Daniel Rubin, Sandy Napel, R. Brooke Jeffrey Jr., Charles Stanley

Volume rendered view of the ankle showing an external fixator (red) attached thru the os calcus (blue). Musculoskeletal imaging remains an important part of the work done in the 3DQ Lab.

Conclusion

During this time of transition with regards to mission and resources, the 3DQ Medical Imaging Laboratory continues to function as an international leader in clinical care, teaching, and research in medical imaging analysis and quantitation. The confluence of talented medical and engineering expertise with the most up-to-date equipment has been a consistent source of innovation in diagnostic, monitoring, and treatment planning approaches.

3D and Quantitative
Imaging Lab

Animal Model Management

Wendy Baumgardner, RVT, LATg
Pam Hertz, RVT

In our continuing efforts to provide support research in the Department of Radiology, we are entrusted with the responsibility of overseeing all animal model protocols within our department and all other departments carrying on research studies at the Lucas Center. Two-experienced California Licensed Veterinary Nurses (RVT), with over 33 years in the field, support all animal model studies with the health and welfare of the animal always our most important priority. Diligent care is taken during all procedures involving animal subjects; they are treated with the utmost respect, compassion, and professional care. Animal studies improve both treatment and diagnostic capabilities for humans, and are managed with the same level of compassion that is extended for our clinical patients.

All personnel working with animal models under approved Institutional Animal Care and Use Committee (IACUC) protocols have completed required training from the Stanford University Department of Comparative Medicine. In addition, specifically tailored “one on one” training for more advanced techniques are taught by the veterinary technicians at the Lucas Center.

We realize that living subjects are needed to advance our knowledge, and to that end we ensure that proper respect for life is part of all research studies. Research conducted at the Lucas Center improves and develops new invasive and non-invasive procedures that utilize Magnetic Resonance Imaging (MRI), High Intensity Focused Ultrasound (HIFU), Computed Tomography (CT), CT/flu-

Licensed Veterinary Technicians Wendy Baumgardner

oroscopy, and Positron Emission Tomography (PET) to guide them. Clinical studies currently conducted include the study of cardiac and liver radio frequency (RF) ablation, myocardial infarction, liver and prostate cancers, neuromodulation with ultrasound, and structural neuroimaging of the brain. The techniques currently being explored at the Lucas Center contribute to more efficient and effective medical treatment for human illness and disease.

Small Animal Imaging Center - SCi3

Tim Doyle, PhD, Head, Small Animal Imaging Facility, MIPS

With demand for small animal imaging by groups in the School of Medicine continuing to increase, the imaging core has responded by upgrading instruments available for use. Dr. Michael Moseley was successful in obtaining an NIH shared instrumentation grant in 2010, which has allowed us to upgrade the 7 Tesla MRI scanner with new gradient inserts and electronics. This upgrade will allow the instrument to be used for animals larger than rats and will provide for overall improvement in imaging protocols. The 7T MRI upgrade is due to be completed at the end of August, 2011. Drs. Christopher Contag and Brian Rutt were instrumental in obtaining a demonstration of a small 1 Tesla MRI system from Aspect Imaging. This system uses permanent magnets that do not require active cooling to operate, and thus functions as a room-temperature bench-top instrument. Extensive use of this magnet for the development of novel MR contrast agents has been made.

Using funds obtained from the School of Medicine, the University, the Stanford Cancer Institute, and the Department of Radiation Oncology, we were able to purchase a new Siemens Inveon MicroPET-CT scanner, which was installed at the end of 2010. This instrument is now available for all users and has resulted in

an increase in MicroPET studies, and nicely complements the older Siemens R4 MicroPET scanner. A bioluminescence microscope was installed in the imaging core, with the LV200 microscope provided by Olympus with funds from the Stanford Cancer Institute used to purchase the Hamamatsu CCD camera. In addition to imaging luciferase-generated photons from cells and tissues, this system has been used to image Cerenkov radiation, a phenomenon in which certain radionuclides emit photons in visible spectrum. In the near future, we hope to install two new photo-acoustic scanners for mouse imaging. Photo-acoustic imaging has recently garnered a lot of interest with Dr. Sam Gambhir’s group pioneering the development of new imaging agents for this modality.

The new small animal imaging facility space in the Larry I. Lokey Stem Cell Research Building (SIM1) opened this year and currently offers access to a Caliper Life Sciences IVIS Spectrum imaging system. This new imaging facility is located within the new Stanford barrier mouse facility and offers imaging capability to animals housed there. We hope that other modalities, such as PET, CT, ultrasound and MR will also soon be available in this new facility.

Lucas Center MR Systems

Anne Marie Sawyer, BS, RT (R)(MR), FSMRT

1.5T, 3T1, 3T2 AND 7T Whole Body Magnets

MRI Systems and Support 2010 - 2011

The 3.0 Tesla #1 G.E. Healthcare MRI system is currently operating at 15.x systems revision; and the 3.0 Tesla #2 GE Healthcare Discovery 750 at 21.x software (Figure 1). The systems operate at a maximum slew rate of 150 Tesla per meter per second and maximum gradient amplitudes of 40 milliTesla per meter at 3T1 and 50 milliTesla per meter at 3T2. The hardware currently allows the use of 16 channels at 3T1 and 32 channels at 3T2.

Figure 1. The ‘3T2’ at the Lucas Center is a G.E. Healthcare Discovery 750 MRI system

Figure 3a and b. a) The new 32-channel phased array MRI head coil from Nova Medical (Wilmington, MA, USA). b) Image acquired with the new Nova Medical 32-channel head coil in the axial plane using a 3D T1-weighted sequence with an in-plane resolution of 430 x 860 microns and a slice thickness of 1.5 mm.

Figure 4. The new Invivo Expression physiologic monitor that includes the following options: wireless ECG (electrocardiogram), wireless SPO2 (heart rate and saturated oxygen), body temperature, invasive blood pressure, NIBP (non-invasive blood pressure), EtCO2 (end-tidal CO2), sedation and anesthesia.

Figure 2. The 1.5T magnet upon being removed from the Lucas Center. The suite is currently under renovation with a planned installation of a G.E. Healthcare 3T Discovery 750 MRI system in September.

The 1.5T MRI system has been removed and renovations of the suite are underway for a new GE Healthcare Discovery 750 at 22.x software with 32 channels to be installed in September of 2011 (Figure 2). The 7.0T MRI system is undergoing a hardware and software upgrade to the GE Healthcare Discovery 950 at 22.x software with 32 channels.

New additions to the MRI systems for use in research studies include a new Nova Medical head coil with 32 channels (Figure 3a and 3b), a new Invivo Expression physiologic monitoring system (Figure 4), and a new EGI 256-channel EEG (electroencephalography) system to be used in the bore of the MRI to simultaneously collect functional MRI data and EEG data.

Daily support in MR system operation and screening and safety is provided to all researchers including faculty, post-doctoral fellows, graduate students, and visiting scholars in the Lucas Center and Department of Radiology; researchers from other University departments such as Psychology, Psychiatry, Neurology, Neurosurgery, and Nephrology; and service center users from outside of the University.

Cyclotron Suite Update

Frederick Chin, PhD
David Dick, PhD

The Radiochemistry Facility (RF) develops and offers radiotracers for early detection and therapeutic monitoring of disease in both preclinical and clinical imaging settings. Our radiochemistry personnel (faculty, staff, and postdocs) continues to number around 30 people including recently hired Amit Hetsron, MS, So-Hee Kim, MS, and Zheng “Ben” Miao, PhD. Additional instruments that were installed in 2010-2011 include two GE radiosynthesis modules (TRACERlab FX-N Pro and FX-FN), two Agilent HPLC with autosampler systems, and a prototype miniature microwave system (CEM PETwave). A clinical radiochemistry laboratory is in the final stages of completion in the new Nuclear Medicine and Molecular Imaging Clinic, which opened in October 2010. This extra lab space will provide clinical-grade radiopharmaceuticals to meet essential clinical radiochemistry demands while abiding by current regulatory policies. The existing radiochemistry labs continue to provide tracers for pre-clinical investigations and maintain our [C-11]carbon dioxide and [F-18] fluorine gas radiochemistries for all our research needs.

Our staff continues to provide routine clinical tracers for use at the Stanford Hospital. Fluorine-18 labeled fluorodeoxy-glucose (FDG) is still produced daily (6-days/week) and is made using the new FASTlab FDG system with much higher yields relative to the MX-FDG module. Nitrogen-13 ammonia (myocardial perfusion assessment) and fluorine-18 sodium fluoride (bone imaging) are also synthesized for the clinic as needed.

Front row (left to right): Amit Hetsron, Frederick Chin, Zheng “Ben” Miao, Michelle James; Back row (left to right): Aileen Hoehne, Bin Shen, David Dick, George Montoya, Mohammed Namavari, So-Hee Kim; Missing from picture: Murugesan Subbarayan

GE TRACERlab modules are the workhorses in the lab and perform the syntheses of our ¹⁸F and ¹¹C-labeled radiotracers for our many collaborations at Stanford and pharma. These modules have enabled us to perform new radiochemistries such as [¹⁸F] FSPG (imaging cystine/glutamate exchanging in tumors) for human studies. Additional PET radiotracers that study the mechanisms and treatment of cancer as well as neurological disorders will soon become available to meet the increasing needs for performing preclinical ([¹¹C]raclopride, [¹⁸F]saxitoxin, [¹⁸F]FBR, [¹⁸F] FTC-146, [¹⁸F]FA-YF₃) and clinical ([⁶⁴Cu]rituximab, [¹⁸F]Avid/ Bayer/GE compounds, [¹⁸F]FSPA-RQ, [¹⁸F]AraG) research studies with PET.

*Pre-clinical and
Clinical Investigations*

Radiolabeled Compounds

The following table presents a summary of radiolabeled compounds that are made in the research radiochemistry lab, excluding research compounds protected under confidentiality agreements (**Bolded tracers** = preclinical and clinical use).

Tracer	Use	Application
[¹¹ C]Raclopride	Imaging dopamine-2 receptors (D2R)	Monitoring D2R-related neurological disorders (i.e. Parkinson’s Disease)
[¹¹ C]PIB	Imaging αβ amyloid in brain	Monitoring progression of Alzheimer disease in brain
[¹⁸ F]CBT	Prosthetic labeling group	Radiolabeling peptides with specific cysteine moiety
[¹⁸ F]AraG	Imaging agent for T-cells	Detection of disease of T-cell origin
[¹⁸ F]FA-YF ₃	Imaging folate receptors	Imaging tumors
[¹⁸ F] FAZA	Hypoxia imaging agent	Evaluating clinical-relevant hypoxia-directed cancer therapies
[¹⁸ F]MISO	Hypoxia imaging agent	Evaluating clinical-relevant hypoxia-directed cancer therapies
[¹⁸ F]EF-5	Hypoxia imaging agent	Evaluating clinical-relevant hypoxia-directed cancer therapies
[¹⁸ F]Fluorouracil	Tumor imaging agent	Evaluating clinical-relevant cancer therapies
[¹⁸ F]fluorobenzaldehyde	Prosthetic labeling group	1) Radiolabeling peptides for potential clinical use 2) Radiolabeled affibody for imaging of NER2neu
[¹⁸ F]fluorobenzoic acid	Prosthetic labeling group	Radiolabeling peptides for potential clinical use
[¹⁸ F]Fluoropropionic Acid	Prosthetic labeling group	Radiolabeling peptides for potential clinical use
[¹⁸ F]SFB	Prosthetic labeling group	Radiolabeling peptides for clinical use
[¹⁸ F]FBR	Imaging agent for TSPO receptors (formerly known as peripheral benzodiazepine receptors)	Monitoring neuroinflammation induced by stroke or radiotherapy
[¹⁸ F]FEAU	Imaging substrates expressing mutant HSV1-sr39tk	1) Monitoring gene therapies targeting cancer 2) Monitoring cell therapies
[¹⁸ F]FHBG	Imaging agent for tumors expressing HSV1-tk	Monitoring various cancer therapies
[¹⁸ F]FLT	Imaging agent for tumor cell proliferation	Monitoring various cancer therapies
[¹⁸ F]FPPRGD2	α,β₃ integrin imaging agent	Imaging tumor integrin expression
[¹⁸ F]FSPA-RQ	Imaging neurokin-1 receptors	Imaging pain and anxiety
[¹⁸ F]FSPG	Imaging agent for cystine/glutamate exchanger	Imaging tumors
[¹⁸ F]FTC-146	Imaging agent for sigma-1 receptor	Imaging agent for studying depression, Schizophrenia, Alzheimer’s Disease, drug addiction, pain, and certain cancers (e.g., prostate, breast)
[¹⁸ F]Saxitoxin	Imaging agent for sodium channels	Imaging agent for sodium channels linked to pain
Other ¹⁸ F-labeled RGD peptides	α,β ₃ integrin imaging agent	Imaging tumor integrin expression

Advanced X-Ray and Computed Tomography (CT) Techniques

Abstracts in this section describe research that is conducted using sophisticated x-ray and Computed Tomography (CT) techniques to improve image quality, decrease the amount of radiation exposure, or reduce the amount of time required to complete an exam. The overall goal of these projects is to improve our ability to detect and monitor disease using these x-ray based methods.

Synthetic CT: Simulating arbitrary CT protocols from a single dual-energy scan

C Feng¹, A Wang^{2,3}, NJ Pelc^{1,2,3}
Departments of ¹Bioengineering, ²Radiology, ³Electrical Engineering, Stanford University, CA

One major goal in CT is achieving adequate visualization of relevant tissue structures at the lowest possible dose. This requires choosing an optimal imaging protocol (kVp, mAs, filtration) in addition to an optimal reconstruction kernel, which is oftentimes difficult to ascertain prospectively due to large variances in patient body structure. Accordingly, we have developed a rapid method and user interface for synthesizing CT images at arbitrary protocols using data from a single dual-energy scan to allow for simulated protocol switching and comparison.

We performed two-material decomposition on axial scans of a phantom acquired on a GE CT750 HD system at 80 kVp and at 140 kVp. By applying estimated source spectra and detector gains to the decompositions, then adjusting the final data to match the expected noise from each synthesized scan, we were able to create realistic images which were indistinguishable from the corresponding actual scans. Furthermore, using the same decomposition data, we were able to estimate dose distribution maps that were very similar to those generated by Monte Carlo simulations.

The clinical utility of our method would be greatly enhanced by rapid interactivity. This requires rapid synthesis of images corresponding to many protocols, and so our algorithms were constrained to a maximum runtime of a few seconds. We were able to accomplish this by using vector calculations and parallel processing, and a dose algorithm estimating the image pixels intersected by each incident ray using both back and forward projection.

Ultimately, our synthetic CT method allows for the rapid determination of optimal scan protocols in addition to allowing users to see how changes in protocol affect visualization. It is our hope that scanning at these optimal protocols in the future will minimize patient dose while maximizing diagnostic efficacy. Our method also allows the simulation of systems that don't yet exist, enabling a prediction of the appearance of clinical images with the new systems.

Our synthetic CT graphical user interface. The left side allows the user to select the imaging protocol and reconstruction parameters, while the right side has two simulated CT scans: an 80 kVp scan (left), and a 140 kVp scan with mA modulation applied (right). On the right side, on top are the reconstructed CT images, while on bottom are the estimated dose maps.

Efficacy of Fixed Filtration for Rapid kVp-Switching Dual Energy X-ray Systems

Y Yao¹, AS Wang³, NJ Pelc^{1,2,3}
Departments of ¹Bioengineering, ²Radiology, ³Electrical Engineering, Stanford University, CA

Purpose: The dose efficiency of dual kVp imaging can be improved if the beams are filtered to increase spectral separation. Since it may not be feasible to have differential filtering for rapid kVp-switching dual energy x-ray systems, we are interested in whether a fixed added filter can improve the dose efficiency of these systems.

Methods: We hypothesized that a K-edge filter would work. Preliminary simulations were done for objects comprised of varying amounts of aluminum and water using 80/ 140 kVp x-ray spectra. The precision of the decomposition based on the propagation of the Poisson noise in the detected intensities through the decomposition function showed that lanthanide elements offer benefit. Considering availability and cost, we finally chose a commercial Gd2O2S screen as our filter for experimental validation.

To gain a more comprehensive understanding of our selected filter on different thickness objects, we made an acrylic-copper step wedge phantom with various combinations of each basis material. We used 70/125 kVp x-ray spectra during the experiment and kept the phantom exposure roughly the same with and without filtration by adjusting the tube current. The variance of the decomposition was measured and the variance reduction ratio of filtered and unfiltered beams was calculated. Simulations were performed with the same experimental settings for validation and to aid in data interpretation.

Results: Simulations showed that the variance reduction monotonically improved as the object becomes more attenuating and the spectra are more separated. The experimental result agreed with this finding, although the measured improvement was somewhat smaller than expected. At more clinical relevant thickness regions, the experiment shows a promising precision improvement with the tested filter.

Conclusions: This study demonstrates the potential of fixed Gd filtration to improve the dose efficiency and material decomposition precision for rapid kVp-switching dual energy systems.

(A) Normalized decomposition variance vs. filter thickness for dysprosium (Z=66). (B) X-ray intensity loss vs. filter thickness for dysprosium (Z=66). (C) Material decomposition noise images: (C.1) Acrylic, without filtration; (C.2) Acrylic, with Gd2O2S filtration; (C.3) Copper, without filtration; (C.4) Copper, with Gd2O2S filtration.

Use of sphere phantoms to measure the 3D MTF of FDK reconstructions

J Baek¹, NJ Pelc^{1,2,3}
¹Department of Radiology, RSL, ²Bioengineering, ³Electrical Engineering, Stanford University, CA

To assess the resolution performance of modern CT scanners, a method to measure the 3D Modulation Transfer Function (MTF) is needed. Ideally, a point object would be used as a test phantom but this is difficult to accomplish experimentally. Recently, Thornton et al. described a method to measure the directional MTF using a sphere phantom [1]. We tested this method for cone-beam CT systems using the well-known Feldkamp (FDK) reconstruction by simulating a sphere and a point object located near the center (0.01 cm, 0.01 cm) and off center in the axial direction (0.01 cm, 0.01 cm, 10.01 cm) and compared the directional MTF estimated from the reconstructed sphere

(a) Estimated MTF along fz axis using a previous method. (b) Estimated MTF along fz axis using a new method.

with that measured from an ideal point object. While the estimated MTF from the sphere near the isocenter showed excellent agreement with that from the point object, the estimated MTF from a sphere offset in the axial direction had significant errors, especially along the fz axis (shown in Figure 1 (a)). We found that this is caused by the long tails of the impulse response of the FDK reconstruction far off the central plane. We developed and tested a new method to estimate the directional MTF using the sphere data. As shown in Figure 1 (b), the new method showed excellent agreement with the MTF from an ideal point object. Caution should be used when applying the original method in cases where the impulse response may be wide.

Comparison of dual kV and photon counting for diagnostic dual energy x-ray imaging

AS Wang^{1,2}, NJ Pelc^{1,2,3}
Departments of ¹Electrical Engineering, ²Radiology, RSL, ³Bioengineering, Stanford University, CA

Dual energy x-ray and CT imaging enable the decomposition of an object into two basis materials. In addition to allowing material specific images, dual energy imaging can allow for contrast enhancement or material subtraction, which can be useful for clinical diagnoses. Dual energy imaging requires measuring the attenuation of the object with at least two different energies. Today’s clinically available implementations use two separate exposures, at a low and high tube voltage (dual kV). Photon counting x-ray detectors (PCXD’s) are an alternative technology that take advantage of an x-ray source’s broad spectrum by counting the number of transmitted photons at each energy from a single exposure. The richness of the information contained in these measurements can depend heavily on the detector’s energy resolution and count rate. Therefore, we seek to compare the material decomposition precision of dual kV with energy integrating detectors to that of realistic PCXD’s.

We study the three primary effects that degrade PCXD performance: count rate limitations, energy resolution, and spectrum tailing. The high flux rates required for clinical imaging pose a serious challenge for PCXD’s, which suffer from count rate losses and pulse pileup if they cannot operate as fast as the transmitted flux. Smaller pixels can reduce the flux per pixel, but increase the effect

On the left, a 150 kVp spectrum is incident on a PCXD, where it is degraded by low energy spectrum tailing (LET). The spectrum then suffers from pulse pileup (right), before the electronics cause a finite energy resolution during readout. The alternating shaded regions indicate the final output counts into 10 bins.

of charge sharing and cross-talk, which increases spectrum tailing. Given these constraints, we found that a well-optimized dual kV protocol performs on par with today’s PCXD’s. For dual kV protocols, it is important to increase the energy separation between the spectra by increasing the kV separation and adding filtration. For PCXD’s, we found it most important to increase the detector’s count rate capability and reduce the spectrum tailing. In conclusion, material decomposition precision can be further improved by either increasing the tube load for dual kV or by using more ideal PCXD’s.

A piecewise-linear dynamic bowtie filter for photon-counting detectors

SS Hsieh, NJ Pelc
Department of Radiology, Stanford University, CA

The bowtie filter in computed tomography systems shapes the intensity distribution across the fan beam of the x-ray beam incident on the patient. Rays that are expected to be highly attenuated by the patient are minimally attenuated by the bowtie, and vice versa, so that ideally the total attenuation for any ray would be as close to constant as possible. This serves to minimize the dynamic range on the detector, to increase the radiation dose efficiency, and to improve image quality by decreasing the harmful effects of scatter. While traditional bowtie filters are helpful, they are designed for a nominal circularly symmetric object and cannot adapt to a specific patient. This limits the achievable dynamic range reduction. We developed a concept that could lead to a dynamic bowtie filter that can morph throughout the course of the scan. It produces a different piecewise-linear attenuation profile at any

Orders of magnitude of attenuation for an example clinical dataset using both the dynamic bowtie and the traditional bowtie. The system with the static bowtie has a dynamic range of 59.3, whereas the dynamic bowtie is able to reduce the dynamic range to 11.8, which translates to a fivefold reduction.

given time thereby achieving a much larger reduction in dynamic range. This additional reduction of dynamic range would be especially welcome in enabling photon-counting detectors. Photon-counting detectors have recently emerged as a potential technology for lowering radiation dose, providing spectral information, and eliminating electronic noise. However, these detectors do not function well when the dynamic range is large due to count rate limitations. Initial studies suggest that the dynamic bowtie is able to reduce the dynamic range beyond that of a conventional bowtie by a factor of five or more depending on the body section studied. Thus, the dynamic bowtie could lead to a relatively simple approach to significantly improve the performance of CT systems.

Early Diagnosis of Pancreatitis in Swine Pilot Study

R Fahrig¹, G Hwang¹, R Hofmann¹, G Glazer¹, T Moore², K Blum¹
¹Dept of Radiology, Stanford University, CA; ²Dept of Computer Science, Siemens AG, Healthcare Sector, Forchheim, Germany

Pancreatic Cancer is among the deadliest forms of cancer, accounting for the fourth lowest survival rate in individuals affected in the United States. A minimally invasive procedure for the possible depletion of pancreatic cancer is controlled tissue ablation within the region of cancerous cells. In particular, Irreversible Electroporation has been successfully demonstrated as a method for non-thermal controlled tissue ablation within the pancreas of swine. However, while successful in the induction of cellular death within well-defined regions of pancreatic tissue, a potential limitation of controlled tissue ablation is the effect on the entity of the pancreas, beyond the focal region. More specifically, alternative methods of controlled tissue ablation--such as injection of ethanol within the pancreas of swine-- have been associated with complications of pancreatitis signaled by an elevation in levels of serum amylase and lipase.

We hypothesize that an increase in the concentration of enzymes or other blood markers could be used as an early marker for pancreatic stress, and

Serum amylase and lipase levels for mild, moderate, and severe cases

therefore could provide a stopping criteria for therapeutic ablation. Specifically, our aim is to evaluate blood serum levels with respect to different stages of pancreatic ablation, in order to investigate Irreversible Electroporation as a possible therapy for pancreatic cancer. Under institutional approval, Irreversible Electroporation was performed within the tail of the pancreas across 3 Yorkshire pigs mean weight: (43.4 kg +2.3 kg). Using C-Arm CT imaging and Ultrasound guidance, 1 lesion (1.0x1.5x1.0 +1 cm) was created within the mild case, 3 lesions (1.0x 1.0x 1.0 + 1 cm) within the moderate case, and 3 lesions (0.5x 0.5x 0.5 + 0.5 cm) within the severe case. Throughout each case, serum was obtained in accordance with the following design: prior to the creation of each lesion (for baseline measurements), immediately following the creation of each lesion, 20 minutes, 40 minutes, and 60 minutes following the creation of the final lesion. As displayed within the corresponding graphs, levels of serum amylase and lipase were sharply elevated at 24 and 48 hours, and normalized by day 7 in all three cases.

Realistic Monte Carlo based simulation of mega voltage computed tomography detectors

D Constantin¹, J Star-Lack², R Fahrig¹
¹Department of Radiology, Stanford University, CA; ²Varian Medical Systems, Palo Alto, CA

It is possible to greatly reduce the incidence of metal artifacts produced in kV-CT images by using megavoltage (MV) photons that penetrate high-Z objects with much less differential absorption than kilovoltage (kV) photons, thus providing a measurable signal. In this sense we propose to develop a greatly improved MV CT detector with high spatial resolution and very high detective quantum efficiency (DQE) that can be integrated with the Electronic Portal Imaging Device (EPID) on a radiotherapy system, to selectively compensate for missing projections and/or rays in images provided by Planning CT or by the on-board kV cone beam CT (CBCT).

The main hypothesis is that the combination of kV-CT imaging with limited MV-CT data acquisition, can largely eliminate the severe image and treatment planning artifacts caused by high-Z objects that are frequently encountered in patients, using a cost effective

Schematic view of a single scintillating crystal with optical photons trajectories (Geant4)

and low added dose approach, based on a novel, high DQE, thin strip of focused scintillator integrated on a standard EPID.

The first step in developing an MV-CT detector was to model different scintillator materials (BGO, CaWO₄, CsI) and inter-septa materials (white plastic or Vikuiti ESR) for a 6 MV spectrum. In this sense we have used existing experimental data for BGO and CsI crystals and we have simulated the active matrixes flat-panel imagers using the Geant4 toolkit. We have determined that the agreement between experimental data, e.g. the presampled modulation transfer function (MTF) or the optical Swank noise factor, is below 2%.

We had to modify the Geant4 toolkit to permit optical photons to cross the inter-septa material thus increasing the optical cross-talk between neighboring pixels. This allowed us to calibrate the optical Monte Carlo based simulations against experimental data, thus providing realistic models for future optimization studies.

Advanced X-Ray and Computed Tomography (CT) Techniques

Robotic linac adaptation (RLA) with a novel electron gun design for the in-line MRI-linac configuration

D Constantin¹, L Holloway², PJ Keall³, R Fahrig¹
¹Department of Radiology, Stanford University, CA; ²Liverpool and Macarthur Cancer Therapy Centres, Liverpool, NSW, AU; ³University of Sydney, Sydney, NSW, AU

The emergence of MRI based guidance systems in radiation therapy has the potential for real-time volumetric imaging and targeting. This work investigates a continuous delivery technique for an in-line MRI-linac system with a non-MR-shielded linac. Similar to the CyberKnife™ system the linac tracks the tumour motion and adapts its orientation in the fringe field of the magnet.

An electron gun model resembling a plane capacitor is proposed to function with an unmodified Varian 600C linac. Space charge and electron transport simulations were used to characterize the electron gun-linac system in the fringe field of a 0.5T open bore MRI scanner (GE Signa SP) at 0.18T. The assembly was displaced off the axis of symmetry and moved along the magnetic field lines to account for tumour motion and the beam characteristics of the systems were determined.

The minimum transverse rms emittance of the beam is ~6.4 π -mm-mrad 4.4mm away from the electron gun cathode with a current of 360mA. This compares favourably with the perfor-

mance of a standard Pierce-type gun placed at the same location in the magnet, which demonstrates significant reduction of current and/or emittance as high as 25 π -mm-mrad. We show that the linac can be displaced off axis with minimal reduction in capture efficiency while maintaining low emittance if the linac is aligned with the field lines. The linac capture efficiency, the beam current at the gun exit, and the beam current at the linac exit were computed within the domain of linac motion.

A specially designed electron gun-linac assembly can function in the fringe field of a MRI magnet for various relative orientations of the linac with respect to the MR scanner. This technique allows the linac to simultaneously deliver dose and continuously track and adapt its position based on tumour motion.

C-arm cone-beam CT for liver perfusion imaging

A Ganguly¹, A Fieselmann^{2,3}, Y Duerling-Zen², J Boese², N Kothari¹, T Moore², K Blum¹, R Fahrig¹
¹Dept of Radiology, Stanford University, CA; ²Siemens AG, Healthcare Sector, Forchheim, Germany, Dept of Computer Science, ³Erlangen Graduate School in Advanced Optical Technologies (SAOT), Friedrich-Alexander University Erlangen-Nuremberg, Germany

Perfusion CT (PCT) imaging of the liver can be a useful tool in the diagnosis and treatment of hepatic carcinoma¹. Availability of intra-procedural PCT imaging can provide valuable information regarding procedural progress and end point determination. Most commonly image-guided interventional treatments use fluoroscopic and angiographic images obtained from C-arm based x-ray systems. Recent systems are also capable of providing cone-beam CT (CBCT) images. However the rotation speed of such systems is slow (~4s) compared to clinical CT (~0.5s). This makes PCT imaging with a C-arm CBCT systems difficult. We have tested a recently reported technique² for imaging following injection of a constant bolus of iodinated contrast and have obtained liver perfusion blood volume (PBV) maps from corresponding CBCT data.

Four anesthetized pigs (52.75±5.27 kg) were imaged using a C-arm CBCT

change is 29.5±33.1%. Obtaining liver PBV maps appears feasible using a C-arm CT system. Ongoing studies involve further optimization of the injection and scanning parameters as well as perfusion flow measurements.

Quantifying the size of a myocardial infarction during an interventional procedure using cardiac C-arm CT imaging

E Girard¹, A Al-Ahmad², D Lee², F Chan³, J Rosenberg³, R Luong⁴, T Moore⁵, G Lauritsch⁶, J Boese⁶, R Fahrig³
Departments of ¹Bioengineering, ²Cardiovascular Medicine, ³Radiology, ⁴Comparative Medicine, Stanford University, CA; ⁵Siemens Medical Solutions Incorporation, Malvern, PA; ⁶Siemens AG Healthcare Sector, Forchheim, Germany

Cardiac C-arm CT is a valuable imaging modality that can provide three-dimensional images of the heart during an interventional procedure. As the technology advances to provide better image quality and faster acquisition times, the potential clinical uses increase. The size and extent of infarcted tissue after an acute myocardial infarction(MI) (heart attack) could furnish early prognostic information for risk stratification and predict functional recovery.

In 12 swine, a coronary artery was occluded with an angioplasty balloon for 60 minutes to create a model of reperfused MI. Iodine contrast-enhanced C-arm CT imaging was performed the day of infarct creation (acute, n=6) or 4 weeks after infarct creation (subacute, n = 6) and the volume of the infarct was compared against pathology to validate the visualization of infarction. Acute MI

is best visualized at 1 minute after contrast injection as a region of combined hyper- and hypoenhancement (mean ± 95% confidence interval: hyperenhancement 36 ± 22 HU; hypoenhancement -65 ± 38 HU) whereas subacute MI appears as a region of hyperenhancement with peak contrast enhancement at 5 minutes post contrast injection (47 ± 14 HU). C-arm CT infarct volumes compared well with TTC staining (acute: range 4.0 – 25.0 cm³, mean 13.1 cm³, mean difference -0.5 cm³; subacute: range 6.2 – 13.4 cm³, mean 9.0 cm³, mean difference -0.7cm³).

In conclusion, cardiac C-arm CT has been established as a consistent and reliable technique for imaging myocardial infarction in the interventional suite. This imaging technique has immediate clinical value providing early information for prognosis and risk stratification. In the future, 3D images of MI could be used for guidance of stem cell and regenerative therapies as well as during the guidance of ablation therapies for ventricular arrhythmias.

3D Knee Geometry under Weight-Bearing Conditions using a C-Arm CT Scanner

J-H Choi³, A Keil¹, A Maier¹, C Niebler⁶, M Sarmiento⁷, A Fieselmann⁶, S Pal⁵, T Besier⁷, GE Gold¹, S Delp^{2,3,4}, R Fahrig^{1,2}
Departments of ¹Radiology, ²Bioengineering, ³Mechanical Engineering, ⁴Orthopaedic Surgery, ⁵Computational Biomechanics Lab, Stanford University, CA; ⁶University of Erlangen-Nuremberg, ⁷Siemens AG, Healthcare Division, Forchheim, Germany; ⁷Auckland Bioengineering Institute, The University of Auckland, Auckland, New Zealand

Recent developments in C-Arm CT provide a promising technique to characterize the knee joint under loaded conditions. We were able to acquire data in a horizontal scan plane for the first time using our C-Arm system. The remaining challenge is compensation for the involuntary tremor of the standing subject during a weight-bearing acquisition. We constructed the 4D Digital Extended Cardiac-Torso (XCAT)-based knee model, and controlled it to behave as a human patient does. Computationally efficient methods for generating 2D projections and volume reconstruction are presented.

We used an 8-camera optical tracking system to capture 9 volunteers' motion at a rate of 120 Hz while standing with 60 degree of knee flexion. We scaled and transformed the knee model to a subject so that its motion with a 6 DOF subject-specific knee joint was synthesized to the subject. The model was tessellated to triangles and 191 projections were generated based on ray casting. Reconstruction was performed using filtered back

projection accelerated using graphics hardware.

Average motion of 2.4 mm (+/- 1.6 mm) was seen at both knees which is about 7 times larger than the detector resolution in 2×2 binning (0.316 mm pixel size). As a comparison, the left leg volumes with and without a subject's tremor were reconstructed. The motion corrupted volume's deviation from the static volume, defined as the root mean square deviation normalized to the mean of each voxel value, is calculated as 41.1%.

From the study, we can estimate potential motion artifacts before actually scanning a human patient. We expect artifacts in reconstructions to be significant for squat positions if no motion correction is applied; the effect will be even worse in patients with knee pain. Recently, we developed marker-based motion correction algorithm which effectively reduces motion artifacts.

Adapted Iterative Methods for Specialized Cone Beam Reconstructions

A Keil¹, J Star-Lack², R Fahrig¹
¹Department of Radiology, RSL, Stanford University, CA; ²Varian Medical Systems, Mountain View, CA

Modern radiotherapy systems rely on the accurate delineation of lesions and critical structures in diagnostic CT images for generating an optimized treatment plan. But the segmentation of these anatomical structures is hampered by reconstruction artifacts. One of the most severe of these artifacts is streaking caused by “photon starvation”, i.e., metal implants attenuating almost all of the incident X-ray photons. This problem is especially relevant in neurology applications in the presence of tooth fillings and for the pelvic region in the case of hip implants. Since this highly non-linear attenuation process is not modeled in standard filtered back projection algorithms, the resulting images are reconstructed based on false assumptions, resulting in the aforementioned streaking artifacts.

Several methods have been proposed to iteratively cope with these artifacts (mostly by interpolating the missing projection data). But the underlying problem of not having reliable data along rays intersecting high-density material cannot be solved without additional measurements for obtaining better attenuation statistics.

Luckily, such measurements are available in modern radiotherapy systems offering to capture images from the high-energy treatment beam. The MeV treat-

ment photons easier penetrate high-density objects thus generating valuable measurement data where the low-voltage diagnostic photons are blocked. The downside of reconstructions purely based on MV photon data is the lower soft tissue contrast resolution. A combination of both input data therefore has the potential to yield reconstructions with improved, artifact-less reconstructions. This should result in better treatment plans with a

better effective dose rate and thus improved treatment outcome for cancer patients with metal implants.

Among the questions to be addressed over the course of this project are an optimization of the MV detector, different approaches of combining the two input data sets, and a better modeling of the physical processes during the image acquisition. Preliminary results already show that a combination of kV and MV data results in drastically reduced artifacts but image quality heavily depends on the spectrum of high-energy photons from the treatment head.

X-ray tube cathode design for operation in the magnetic field of an MR imaging system

P Lillaney^{1,2}, R Fahrig¹
Departments of ¹Radiology, ²Bioengineering, Stanford University, CA

The purpose of this study is to evaluate the effectiveness of electrostatic mechanisms for controlling electron trajectories in X-ray tubes operating in the fringe field of an MR bore, and to determine a cathode design to implement the correction mechanism while not compromising normal X-ray tube operation.

Using a combination of theoretical calculations and high voltage vacuum standoff constraints, a cathode design is derived that is practical for standard X-ray tube geometry. The crucial part of the design consists of two voltage-biased deflection electrodes placed adjacent to the cathode. Space charge beam simulations are performed for the design to determine current density changes and beam deflection in the presence of a magnetic field. Phase space information from the beam simulation is input into a Monte Carlo engine to determine the effect of the cathode design on the X-ray photon energy spectrum.

For a 0.07T magnetic field, a 120 kV cathode-anode potential, a 14.4 mm cathode-anode separation distance, and a 35 kV electrode bias potential, the deflection

Left half of the figure displays a three dimensional model of the revised cathode design. The bias electrodes are shown in blue with the filament positioned in between. The electrodes are held in position by a ceramic backing. Right half of the figure displays two sets of simulated electron trajectories. The top is the control simulation, while the bottom is the simulation with a 0.07T magnetic field and a 35 kV electrode bias potential.

of the X-ray tube focal spot is within 2 mm of the original position with slight distortions to focal spot shape. However, the increased curvature of the electron trajectories results in a tangential velocity 10 times larger than the control case. The electron velocity changes coupled with slightly lower current density on the anode reduces the total number of photons generated by 7.5% without significantly altering the energy spectrum of the X-ray photons.

In conclusion, the electron beam simulations demonstrate that focal spot deflection can be controlled to within reasonable values. The generated spectrum is not significantly different from that of a standard X-ray tube, with only a moderate decrease in overall photon fluence. Work is underway to evaluate the cathode design in an experimental setting.

Modal analysis of both conventional and modified MR compatible x-ray tubes

M Shin^{1,2}, R Fahrig¹
Departments of ¹Radiology, RSL, ²Mechanical Engineering, Stanford University, CA

A rotating anode x-ray tube design consisting of a 3-phase MR compatible motor was developed and the mechanical resonance frequencies of the structure were analyzed. Qualitatively speaking, it is better to have a higher fundamental resonance frequency, since it allows for a larger range in stable rotation speeds.

Based on our finite-element analysis it was determined that a conventional x-ray tube has a fundamental resonance frequency of 87.75Hz (5265rpm); which agrees with literature values. While the conventional tube is mostly made out of steel, our new x-ray tube is mainly composed of ceramic (MACOR). Overall diameters of the structures are also different: 1.47 in for the conventional tube and 2.9 in for the new tube design. Our new rotating anode x-ray tube design has a reso-

Modal analysis for x-ray tubes. (a) 2D view of COMSOL 3D model for a conventional x-ray tube, (b) 2D view of COMSOL 3D model for an improved 3-phase MR compatible x-ray tube.

nance frequency of 40.76Hz (2445.6rpm). Since we plan to operate the tube at speeds higher than 2500 rpm we must revise the design in order to increase the fundamental resonance frequency. We can change several factors such as cross-sectional area, stress concentration, and distribution of materials. An improved design with a larger anode shaft and chamfers yields a resonance frequency of 57.14Hz (3428.4rpm).

Based on FEA thermal analysis, we know that a larger diameter of the anode shaft conducts more heat from the anode to the other parts of the structure. When the anode reaches steady state, the highest temperature of the rotor is about 100°C. The resultant temperature needs to be decreased to reduce mechanical stress on the brittle ceramic material. Future work will focus on balancing the resonant frequency and temperature trade-off.

In this section, you will read about innovations in display and interaction, feature extraction, and computer simulation and modeling techniques. These projects aim to improve the accuracy and efficiency of human interpretation of medical imagery, as well as predict patient prognosis, the molecular subtypes of their disease, and their response to treatment options in a way that is highly personalized for each patient. These efforts share the common goal of developing decision-making tools that assist with patient diagnosis, treatment, and disease monitoring.

Topological analysis of ARACNE networks on Acute Myeloid Leukemia data

A Babu¹, G Carlsson², A Gentles³, S Plevritis³
¹Institute for Computational and Mathematical Engineering, Departments of ²Mathematics, ³Radiology, Stanford University, CA.

We analyze the structure of gene interaction networks using the MAPPER algorithm. MAPPER visualizes large, high-dimensional geometric objects as small networks(graphs) that capture the overall structure of the original object. The visualization is done with respect to a certain orientation of the geometric object (i.e. a height function). Different orientations of the object reveal different structural information. We apply MAPPER to visualize gene expression (ARACNE) networks after first converting them into geometric objects via a kernel embedding technique.

This process summarizes the original network by collapsing all the non-hub genes into a single node in the summary network. Hub genes are collapsed into sets of ‘nearby’ hub genes, each set being represented by a node. The hub-ness or the centrality of a gene is not determined solely by the number of genes connected to it(degree), but also by the centrality of the nodes it connects to. The summary network retains the information about the interrelationship (the network connectivity structure) between the hub genes, which is the high-level topology of the original network.

The above process being run on three AML public gene expression datasets, generated by Metzeler et al., Tomasson et al. and Wouters et al., reveals

First row: Summary networks for the Metzeler et al., Tomasson et al. and Wouters et al. AML gene expression datasets (left to right). The individual flares are sets of hub genes. Metzeler et al. has five such sets, Tomasson et al. one and Wouters et al. two. The dark blue node in each summary network represents all the collapsed non-hub genes. Second row: Correspondences between the summary networks; first Metzeler et al. vs. Tomasson et al., second Metzeler et al. vs. Wouters et al. The dark blue node is essentially the same across the networks this correspondence is indicated by an arrow between the dark blue nodes. The other arrows show the correspondences between the sets of hub genes.

tivity between the hubs is simple and is preserved across datasets. Currently we are attempting to combine the above analysis with the notion of intramodular hub genes, which are of high biological significance.

Simulation modeling of the impact of prophylactic surgery on life expectancy in BRCA1/2 mutation carriers

DF Munoz¹, BM Sigal¹, AW Kurian^{2,3}, SK Plevritis¹
Departments of ¹Radiology, ²Health Research and Policy, ³Medicine, Stanford University, CA

Women with BRCA1/2 mutations cancer susceptibility genes are recommended a number of intensive risk-reducing strategies to manage their high risks of breast and ovarian cancer, including prophylactic surgery and screening. However, there remains significant controversy about the overall health benefits of these procedures. Building upon previous work, we report the methodology developed to build a Monte Carlo simulation model that computes the life expectancy of women at different ages, who choose to undergo prophylactic mastectomy (PM) and/or prophylactic oophorectomy (PO) immediately, or delaying the procedure 5, 10 or 15 years after their BRCA1/2 mutation is detected.

The benefits of the evaluated alternatives are measured in terms of life years gained with respect to the case in which

Expected lifetime of 30, 40 and 50 year-old BRCA1 (top plots) and BRCA2 (bottom plots) mutation carriers under different strategies, including prophylactic mastectomy (PM), prophylactic oophorectomy (PO) and screening with mammography and magnetic resonance imaging (S). All scenarios include screening, performed from the moment of BRCA status determination until age at PM or at age 70, whichever comes first. For all 3-carrier ages, the “No Intervention” scenario (black line with solid dots) shows the baseline expected lifetime where no intervention is pursued.

A leukemic stem cell signature predicts outcome in Acute Myeloid Leukemia

AJ Gentles¹, SK Plevritis¹, R Majeti², AA Alizadeh²
Departments of ¹Radiology, ²Internal Medicine, and Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, CA.

In many cancers, specific subpopulations of cells appear to be uniquely capable of initiating and maintaining tumors. The strongest support for this cancer stem cell model comes from transplantation assays in immune-deficient mice indicating that human acute myeloid leukemia (AML) is organized as a cellular hierarchy driven by self-renewing leukemia stem cells (LSC). This model has significant implications for the development of novel therapies, but its clinical significance remains unclear. We defined a gene expression signature of LSC-enriched subpopulations from primary AML patient samples and xenografts, based on a functional definition in transplantation assays. Using previously published gene expression data of bulk AML from four independent cohorts totaling 1047 patients, we defined an LSC score and eval-

Association Between Leukemic Stem Cell (LSC) Score and Survival Outcomes in Patients With Normal Karyotype Acute Myeloid Leukemia (AML).Stratification of outcomes using this approach is depicted for overall survival in the training set and in one of the validation sets and event-free survival in one of the validation sets. Vertical ticks on curves indicate censored events. Similar results were obtained in the other independent data sets

uated it for associations with known predictors of risk including cytogenetic subtype and molecular mutations, and as an independent prognostic factor. The LSC score was similar across most AML subtypes, but was lower in promyelocytic leukemia, and prognostically favorable cases harboring NPM1 or CEBPA mutations. Strikingly, high scores predicted inferior overall (OS), event-free (EFS), and relapse-free survival (RFS) in these independent cohorts, whether considering patients with a normal karyotype, or those with cytogenetic anomalies (HR range for OS 1.07-1.15, p<0.01 in all cases). In multivariate analysis, the LSC score predicted poor outcomes independently of age, FLT3 or NPM1 mutations, and cytogenetic risk group, and added to their prognostic value.

Image Analysis, Bioinformatics, and Computational Modeling

Global cancer map of associations between gene expression and survival outcomes

AJ Gentles¹, S Smits¹, AA Alizadeh², SK Plevritis¹
Departments of ¹Radiology, ²Internal Medicine, and Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, CA

A common use of high-throughput cancer datasets is to identify genes whose expression or mutational status is prognostic of patient survival. However, such “gene signatures” are often difficult to interpret in terms of the underlying biology. Moreover, lack of reproducibility often arises due to differences in patient populations, treatments, and technological platforms. In recent work we found that expression of a group of genes defined by their expression in purified leukemic stem cell (LSC) populations is reproducibly associated with patient survival across multiple studies in acute myeloid leukemia (AML). I will describe how meta-analysis of hundreds of public datasets can be applied to implicate which biological processes and cell sub-populations drive clinical outcomes in cancer. Both cancer-wide and cancer-specific robust patterns emerge. Induc-

Association of gene expression levels with cancer clinical outcomes across multiple cancer datasets. Each row represents a gene, and each column a study. Red indicates that high expression of a gene is associated with poor outcome (shorter survival). Green indicates that high gene expression associates with better outcome. ALL=acute lymphocytic leukemia, AML=acute myeloid leukemia, CNS=central nervous system tumors, Mel=melanoma, Ova=ovarian cancer.

tion of pluripotency and blocks in differentiation are implicated in poor outcomes across a range of malignancies. Conversely, infiltration of particular immune cell populations, and activation of specific pathways within them, predict good outcomes.

Application of this approach to AML identifies a DNA damage response that, when over-expressed in LSC, is associated with worse patient survival. The same pathway is utilized in protecting normal hematopoietic stem cells from damage induced by reactive oxygen species. This suggests that its over-expression in LSC may confer them with the ability to resist death due to therapy-induced DNA damage, leading to treatment failure and disease relapse.

The regulatory network of T cell acute lymphoblastic leukemia

O Gevaert¹, A Gentles¹, J Meijerinc², SK Plevritis¹
¹Department of Radiology, RSL, Stanford University, CA; ²Department Pediatric Oncology/Hematology, ErasmusMC Hospital, Netherlands

Pediatric T cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematological malignancy of thymocytes that amounts to 10-13% of all ALL cases and is often fatal without therapy. A number of genetic abnormalities have been identified that transform normal T-cells to a malignant phenotype in a mutually exclusive way. These abnormalities include translocations, duplications, deletions, amplifications and mutations that results in expression of TAL1, TAL2, LMO1, LMO2, HOXA, TLX1 or TLX3 genes which arrest T-cell differentiation at different stages of T-cell development. Microarray studies have confirmed that these abnormalities direct T-ALL to different subgroups with the same transcriptional response, e.g. TAL1, TAL2, LMO1 and LMO2 form the TALLMO group with a similar transcriptional response while HOXA, TLX1 and TLX3 form other subgroups with distinct transcriptional profiles.

Treatment depends heavily on the subgroups classification, therefore it is important to understand what makes these subgroups differ on a transcriptional level and which mechanisms are driving T-cells to a malignant phenotype. Currently however not much is yet known about the regulatory network that is responsible for these mutually exclusive subgroups. Much of the previous research

The regulatory network of T cell acute lymphoblastic leukemia built using a module network approach based on elastic net regularized linear regression.

has focused upon defining subgroups and developing classification models based on a small subset of genes to classify T-ALL patients into the subgroups.

We have used a module network approach in combination with regularized linear regression to model the transcriptional program of T-ALL. More specifically we have used a previously developed approach that uses elastic net regularized linear regression to model the regulatory program. This regularization approach allows accommodating for correlated regulators while still forcing the regulatory program to be sparse. In addition we used the same methodology to model the relationship between the modules and the genetic subgroups. We applied this method on a set of 117 patients

that were profiled with microarray technology. Our results show that modules were identified related to the different subtypes of T-ALL which are regulated by T-ALL genes such as TLX1, TLX3. In addition our analysis enables us to make several hypothesis about regulatory interactions in different T-ALL subtypes and are in the process of validating them both computationally and experimentally.

Evaluating the Impact of Hormone Therapy on Breast Cancer Incidence

Y Guan¹, SK Plevritis²
Departments of ¹Management Science and Engineering, ²Radiology, Stanford University, CA

Postmenopausal hormone therapy (PHT) is now widely recognized as a risk factor of breast cancer, however its effect on the pathogenesis and progression of the disease is not fully understood. We hypothesize that changes in US breast cancer incidence and mortality rates following changes in PHT use may provide insights. After the release of the 2002 report of the Women’s Health Initiative (WHI) trial of estrogen plus progestin, the use of PHT in the U.S. reduced remarkably. Subsequently, a reduction in breast cancer incidence was observed in the Surveillance, Epidemiology and End Results (SEER) program of the NCI for the year 2000-2005, further implicating a cause-and-effect relation between HT and breast cancer. Our study aims to quantify the effect of PHT on breast cancer incidence using a

Comparison of SEER data and model-predicted age-adjusted breast cancer incidence (top panel) rates of age group 50-69, with two scenarios considered: with PHT effect and without PHT effect.

stochastic simulation model of the impact of PHT on the natural history of breast cancer. We assume that PHT only effect the progression of breast cancer and does not initiate new cancers. Under these assumptions, we estimate the relative impact of PHT use on the mean tumor volume doubling time and the median tumor size detectable on a mammogram. The estimates of PHT’s effect are calculated by calibrating the predicted breast cancer incidence and mortality rates to actual rates from SEER database. We find that the discontinuation of PHT use causes a rapid drop in breast cancer incidence, consistent with the SEER data. Our preliminary results support the hypothesis that PHT use increases breast cancer incidence through accelerating tumor growth and affecting mammographic tumor detectability.

Application of Stochastic Modeling to Simulation and Analysis of Mayo CT Lung Cancer Screening Trial

SA Erdogan, W Wan, RS Lin, EB Tsai, SK Plevritis
Department of Radiology, Stanford University, CA

Lung cancer is the leading cause of cancer-related deaths among both men and women, for which the 5-year survival rate is only 3.5%. Screening has only recently been shown to provide benefits in mortality reduction through repeated low-dose CT imaging; however, this benefit has not been fully explored in the Mayo CT lung cancer clinical trial, which lacked an unscreened control arm. We aim to simulate the results of the Mayo CT trial using a natural history model to analyze effects of CT screening on incidence and mortality.

A stochastic model of the natural history of lung cancer was used to estimate the likelihood of cure as a function of tumor size. Parameters were estimated based on the Surveillance, Epidemiology and End Results (SEER) cancer registry. Results were first externally validated against the control

Observed incidence and mortality results of Mayo CT trial vs. expected incidence and mortality results of simulation with Mayo CT cohort distribution and compliance (blue) and even cohort distribution and perfect compliance (red), both in presence and absence of screening.

arm of the Mayo Lung Project. For this simulation, screening, follow-up, and treatment components were implemented into the model based on published protocols matching those used in Mayo CT diagnosis and treatment.

Our simulation models show adjusted incidence rates of 26-42 cases over the 5-yr duration of the trial (compared to 68 actual cases in Mayo CT) depending on 1) age distribution of trial participants, and 2) level of adherence to scheduled screening. Annual interval screening increased detection of lung cancer by 80% and reduced 5-yr mortality by 23% compared to the simulated, unscreened cohort. Further efforts in model refinement will clarify the exact benefits and the impact of screening on overdiagnosis and false positives.

TreeViz: A graphical tool for tree visualization

P Qiu, SK Plevritis
Department of Radiology, Stanford University, CA

Network-based analyses of high-dimensional biological data often produce results in the form of tree structures. Generating easily interpretable layouts to visualize these tree structures is a non-trivial task. We present a new visualization algorithm, TreeViz, to generate two-dimensional layouts for complex tree structures.

TreeViz emphasizes the longest path and major branches of a tree structure. Given the adjacency matrix of a tree structure, TreeViz first identifies the longest path, and rearranges the nodes along it into an arch-like shape. Then, the remaining nodes are ordered and sequentially appended. The ordering of the tree nodes is derived as follows: TreeViz breaks the tree into chains of nodes. The longest chain is defined as the main chain. Chains that are directly connected to the main chain are defined as the side chains. For complex tree structures, each side

MATLAB graphical user interface of TreeViz.

chain can also have its own lower level side chains. Tree nodes are arranged in an order such that nodes in the main chain come first, followed by nodes in the side chains, and then the lower level side chains.

After ordering the tree nodes, TreeViz rearranges nodes in the main chain on an arch-like curve, with unit distance between adjacent nodes. The remaining nodes are appended one at a time, according to the ordering defined above. Between the new node and each existing node, we assume a repelling force, which is inversely proportional to their distance. Each edge is assumed to be a string whose length is less than or equal to unit distance. Since the new

node is attached to one of the nodes that are already visualized, the position of the new node is within a unit radius disk of its visualized neighbor. TreeViz exhaustively examines all positions within this unit disk, and places the new node at the position where it is under balanced forces.

SPADE: Spanning-tree Progression Analysis of Density-normalized Events

P Qiu¹, EF Simonds², SC Bendall², K Gibbs², MD Linderman³, K Sachs², GP Nolan², SK Plevritis¹
Departments of ¹Radiology, ²Microbiology and Immunology, ³Computer Systems Laboratory, Stanford University, CA

Flow cytometry captures the heterogeneity of biological systems by providing multiparametric measurements of individual cells. Traditional analysis of cytometry datasets is a subjective process that requires extensive familiarity with the biological system. We present a novel computational approach, Spanning-tree Progression Analysis of Density-normalized Events (SPADE), to identify and visualize branched differentiation hierarchies in multidimensional flow data, without requiring prior knowledge about the developmental hierarchy in the data. SPADE enables several novel approaches for cytometric analysis, including merging of overlapping reagent panels and direct comparison of marker intensities across multiple datasets. We applied SPADE to conventional (8-parameter) and next-generation (31-parameter) cytometry data of mouse and human bone marrow. In both datasets, SPADE detected a differentiation hierarchy which recapitulates well-described patterns of hematopoiesis. From the conventional flow dataset, SPADE identified major cell types

(a) Simplified mouse hematopoietic hierarchy underlying a mouse bone marrow flow dataset, and the tree structure derived by SPADE. The tree was color-coded by median intensities of one individual marker, to show how markers behave across the tree. (b) Traditional gating analysis of the mouse bone marrow data. To illustrate the concordance between SPADE and gating, for each gated population, the SPADE-derived tree was drawn, where each node was color-coded by the percentage of gated cells in that node.

References/Funding Source

U54CA149145

of mouse bone marrow, and the findings were confirmed using a traditional analysis method, namely gating (results shown in figure). By exploiting the high dimensionality of next-generation cytometry data, SPADE defined a functionally distinct cell population in human bone marrow, using subtle differences in marker expression, even in the absence of a population-specific marker. This population was then inferred to be NK cells based on additional surface markers from an automatically merged second staining panel. By reserving a set of functional markers in the tree-building step, we used SPADE to map intracellular signal activation across the landscape of human hematopoietic development. SPADE is a versatile tool for analysis of multidimensional flow cytometry, facilitating de novo discovery of developmental transitions, automated comparison of functional markers, and identification of rare or malignant cell populations.

RED-SIGN: REconstructing Directed Signed Gene regulatory Network from microarray data

P Qiu, SK Plevritis
Department of Radiology, Stanford University, CA

Great efforts have been made to develop both algorithms that reconstruct gene regulatory networks, and systems that simulate gene networks and expression data for the purpose of benchmarking network reconstruction algorithms. An interesting observation is that although many simulation systems chose to use Hill kinetics to generate data, none of the reconstruction algorithms were developed based on the Hill kinetics. One possible explanation is that, in Hill kinetics, activation and inhibition interactions take different mathematical forms, which brings additional combinatorial complexity into the reconstruction problem.

We propose a new model that qualitatively behaves similar as the Hill kinetics, but has the same mathematical form for both activation and inhibition. Based on our new model, we tailored an algorithm RED-SIGN to reconstruct gene regulatory networks, where we can predict the directions, signs and weights of the reconstructed edges. Extensive simulations demonstrated the superior performance of RED-SIGN. Simulation results suggested that in gene knockout experiments, repressing protein synthesis to a certain extent may lead to better expression data and higher network reconstruction accuracy.

Reconstruction accuracy of networks with different regulation strength. γ is inversely related to the regulation strength.

Rapid identification of prognostic imaging biomarkers by leveraging public gene expression data

O Gevaert¹, J Xu², C Hoang^{3,4}, A Leung¹, Y Xu³, A Quon¹, DL Rubin¹, S Napel¹, SK Plevritis¹
Departments of ¹Radiology, ²Electrical Engineering, ³Cardiothoracic Surgery, Stanford University, CA; ⁴Veteran's Affairs Palo Alto Healthcare System, Palo Alto, CA

Personalized medicine aims to tailor medical care to an individual's need through recognition of biological heterogeneity in patients. Current technologies however require invasive biopsies that are not necessary representative of the disease. Medical imaging is non-invasive and also gives anatomical, morphological and physiological information. We propose to harness this information by creating a radiogenomic map that associates medical imaging data with publicly available high-throughput molecular data with clinical outcome. This allows to link imaging data with clinical outcome without the need for follow-up data.

We demonstrate our approach on non-small cell lung carcinoma patients for whom CT, PET/CT and gene expression data were obtained. We extracted 149 computational features, 30 semantic features and PET-SUV from the imaging data. The microarray data was processed using an advanced clustering algorithm and 56 high quality clusters were represented using metagenes. We found several though provoking associations between imaging features and metagenes. 115 of 180 image features were predicted by a sparse regression on 56 metagenes with an accuracy of 65-86%. After mapping

Modeling image features in terms of metagenes.

(A) Strategy for multivariate modeling of image features in terms of metagenes. Each image feature is modeled as a linear combination of metagenes using L1-regularization to induce sparsity in the number of metagenes that are selected. I_i represents the i -th image feature, M_j represents the j -th metagene, f_i represents linear regression for the i -th image feature, α is the regularization parameter, W_j (not shown) represents the weight for each metagene M_i , and W represents the matrix with all weights. (B) Semantic features predicted by metagenes with an AUC of 65% or greater, based on leave-one-out cross-validation (LOO-CV) analysis. AUC stands for Area Under Curve for the Receiver Operating Characteristic (ROC) curve. (C) ROC curve for the predicted presence vs. absence of internal air bronchogram on CT, when expression in terms of metagenes. (D) Multivariate metagene prediction model for the presence vs. absence of internal air bronchogram on CT. The top 7 metagenes are shown representing 95% of the weight of the multivariate model; the top 3 metagenes are up-regulated when an air bronchogram is present, and the bottom 4 metagenes are down-regulated. The down-regulated metagenes are enriched in hypoxia related pathways; the up-regulated metagenes contain a RAS signature and genes up-regulated by RAS. (E) Multivariate model for internal air bronchogram corresponding to (D). For gene expression, red represents over-expression and green represents under-expression; for image features, blue denotes absence of feature and yellow presence of image feature.

Estimating Breast Cancer Survival by ER Molecular Subtype in the Absence of Screening and Treatment

DF Munoz, SK Plevritis
Department of Radiology, Stanford University, CA

The relative contributions of screening and treatment on biomarker-specific breast cancer survival curves is not well characterized because many of the biomarkers that are of interest today were not routinely collected in the absence of screening. Estimates of breast cancer survival in the absence of screening may be found from SEER data from the years 1975 to 1979, but a limitation of this data is that biomarkers, such as ER-status, were not registered at that time. ER-status is being collected by SEER starting 1990 hence, ER-specific survival curves are confounded by screening and treatment effects. We present a modeling approach to back-calculate ER-specific survival curves in the absence of screening and treatment, then compute the relative contributions of screening and treatment on the ER-specific survival curves. Our approach makes use of a previously developed Monte Carlo simulation model that generates the life and screening histories of individual level patients, and determines ER-status by matching

Comparison of ER+ (top plot) and ER- (bottom plot) survival curves versus SEER ER-specific survival curves from years 1990-2006. Our model's ER-specific survival curves are given under 4 different scenarios: in the absence of both screening and treatment, in the presence of screening and the absence of treatment, in the absence of screening and the presence of treatment and the presence of both screening and treatment.

screening and tumor characteristics with estimates calculated from clinically observed BC patients. Running the simulation long enough provides us with a simulated database of BC patients tagged with ER-status, from where it is possible to back-calculate ER-specific survival in the absence of screening and treatment. Subsequently, these survival curves are then used to validate our model when run in the presence of screening and treatment. Knowledge of ER-specific survival curves in the absence of screening and treatment is not only valuable to determine the underlying differences between disease subtypes, but also form to fundamental inputs to models which aim to predict future US breast cancer trends with changes and advances in screening and adjuvant therapy.

A Web-based Method to Disseminate Radiology Appropriateness Criteria for Decision Support

DL Rubin¹, A Walvekar²
¹Department of Radiology, Stanford University, CA; ²The Harker School, San Jose, CA

Purpose: With the explosion in radiology imaging, there is pressing need to ensure it is ordered appropriately. Radiology appropriateness criteria are being developed, but it is challenging to ensure physicians are aware of them when ordering imaging. Our goal was to develop a Web-based mechanism to disseminate, operationalize, and evaluate radiology appropriateness criteria in clinical practice. Method and Materials: We encoded portions of a subset of the ACR appropriateness criteria for a variety of clinical conditions in the Semantic Mediawiki (a semantic implementation of the wiki used to host Wikipedia). We created 100 clinical case scenarios for which these appropriateness criteria would guide physician practice. We matched each case to the appropriateness criteria such so that the Web application could provide decision support on exam appropriateness for each case. We recruited 4 medical residents and asked each to select the single most appropriate test for each clinical case (each resident did the task independently). Two months later the residents repeated the task on the same cases, in random order from previ-

Wiki-based automated decision support application shows the user the potential radiology exams that may be ordered in the given clinical context, with the appropriateness rating ("Rating") and relative radiation level ("RRL").

ously, with our web-based decision support system. The rating of the appropriateness the exams they ordered was evaluated against the ACR criteria and compared with and without decision support using Student's t-test. Results: Without decision support (baseline performance), the average resident appropriateness of exams ordered was 5.26 (SD 3.18), significantly lower than optimum ordering appropriateness by ACR criteria (mean 8.04, SD 1.68). However, the appropriateness of their ordering increased significantly with the Web-based support (mean 5.75, SD 3.21, p < 0.03). All residents reported that the Web-based decision support was highly intuitive to use and they reported that using it would not hinder their workflow. Conclusion: A Web-based wik methodology facilitates electronic encoding and distribution of radiology appropriateness criteria, and resulted in significantly increased practitioner radiology order appropriateness.

Radiological Assessment of Cancer Lesion Response and Comparison of Alternative Metrics Using Web-based Tool

AC Abajian¹, DL Rubin²
¹Department of Medicine, Yale Medical School, New Haven, CT; ²Department of Radiology, Stanford University, CA

Background: A crucial challenge for radiologists is to determine whether cancers are responding to treatment and to be able to compare alternative measures (e.g., linear dimensions of RECIST against area/volume, etc). Our goal was to develop a tool to facilitate radiologist assessment of cancer lesions response as well as comparison of alternative quantitative tumor response metrics. Evaluation: Our system adopts the Annotation and Image Markup (AIM) standard of caBIG. We created an XML database and a PACS database. In our paradigm, the radiologist annotates images using an AIM-compliant image viewing workstation. Our system reads the AIM files, extracts the quantitative image information, and overlays it on the corresponding images retrieved from the PACS archive (Figure). We evaluated our system in a CT imaging study of a patient who had one baseline and two follow up scans and it successfully produced an automated summary of response. Discussion: Our system may provide a better mechanism for radiologists to evaluate temporal imaging studies in cancer patients than the current practice which lacks summarization of the quantitative measurements. Our approach provides a streamlined mechanism for radiologists to interpret oncology studies and provides researchers with a tool to identify better quantitative measures of response than RECIST. Conclusion: We developed a system to generate a graphical summary of cancer lesion measurements from radiology images which may enhance radiology interpretation, clinician interpretability, and clinical care.

Screenshot of our application for automating assessment of cancer lesion response to treatment. All values shown are automatically generated based on query to machine-accessible semantic annotations (in AIM format) on images. The user has selected a patient and evaluation metric (top) and a table summarizing lesions and measurements is provided (left). A graph showing treatment response based on summed length is also shown (right). This type of automated display will likely greatly facilitate summarizing of large serial imaging studies and enable rapid comparison of alternative quantitative image metrics of cancer response.

ePAD: A Cross-Platform Semantic Image Annotation Tool

DL Rubin, A Snyder
Department of Radiology, Stanford University, CA

Background: The cancer Biomedical Informatics Grid (caBIG) Annotation and Image Markup (AIM) standard can empower the radiologist by enabling image metadata access, exchange, and usage; however, AIM is generally not accessible in clinical practice since vendor adoption in clinical workstations is slow and variable. Our goal is to provide a freely-accessible method of universal radiologist access to AIM benefits in a cross-platform tool that can be integrated into all radiology workstations. Evaluation: We have created ePAD (the electronic Physician Annotation Device), an implementation of AIM in a rich Web client architecture. ePad a freely-available tool that runs on modern Web browsers and provides semantic image annotation on any platform and within any image workstation environment, including the Apple iPad. The ePAD tool consumes images within any image viewing workstation, it extracts the quantitative information from radiologist annotations on the images, and it and saves these image metadata in AIM. Communication of ePAD and the workstation occurs via a proxy; we are also developing vendor-

The ePAD tool is a rich Web application that runs in a Web browser on any platform. Radiologists can access, view, and annotate image obtained from their PACS, save the image metadata in the standard AIM image metadata format, and access the benefits of AIM metadata interoperability.

specific API calls where available to make the integration even more seamless. This exhibit will show the features and operation of ePAD and potential benefits to radiologists. Discussion: Developments in quantitative imaging are occurring rapidly, but improved radiology practice is thwarted by slow and variable vendor adoption of cutting-edge advancements. Our rich Web-based image viewing architecture enables new tools such as AIM to be executed on any platform, including vendor workstations, provided they run a Web browser. Ultimately, we foresee a paradigm where semantic image annotation and capture of machine-accessible image content via AIM will be as seamless as DICOM implementations currently provide with image data. Conclusion: We developed a cross-platform Web-based image viewing/semantic annotation tool to enable radiologists to access the benefits of image metadata collection/exchange in clinical practice. We believe this approach will catalyze adoption and dissemination of the AIM standard and empower radiologists with the benefits of image metadata sharing and interoperability.

Active Feature Acquisition Using Sensitivity Analysis to Classify Mammography Reports

F Gimenez¹, DL Rubin²
¹Biomedical Informatics Training Program, ²Department of Radiology, Stanford University, CA

Purpose: We present a method to automatically select a subset of BI-RADS observations for use in prediction of diagnostic codes in mammography reports. This method is optimized to rapidly converge to high classification accuracy with a small number of radiological annotations.

Method and Materials: 7,468 unilateral diagnostic mammography reports containing BI-RADS codes between 1-6 were obtained from the Stanford RADTF database. BI-RADS observations were extracted from free text reports using natural language processing techniques that account for misspellings, ambiguous term usage, and negation. There are 48 possible observations which were concatenated into a binary feature vector to indicate their presence in a report. Reports were stratified into 3 classes: Class 1 containing reports with ratings 1 and 2, Class 2 containing reports with ratings 3 and 4, and Class 3 containing reports with ratings 5 and 6. Under this categorization, classes can be interpreted as benign, abnormal, and at risk. A Naïve-Bayes classifier was trained to predict the BI-

RADS diagnostic code from the feature vectors. Single features were progressively selected maximize the first-order Sobel (FOS) score of the output class. Reports were classified using this smaller subset of features.

Results: First-order Sobel indices are meant to reduce variance in the output class rapidly. We plotted the variance with respect to the number of features selected. Results show an exponential drop in variance compared with the linear decrease of random feature selection. A signed rank confirmed that the difference was statistically significant ($p=7.8E-260$). We then plotted the classification accuracy with respect to features used. Once again, the plot shows the classification improving as a function of features selected.

Conclusion: We have demonstrated a method to automatically select BI-RADS observations with relation to their importance in classification accuracy. Such a method can be used to reduce workload on radiologists while ensuring unambiguous reporting.

Using the Semantic Web for Radiology Decision Support of Focal Liver Disease

I Djomehri, DL Rubin
Department of Radiology, Stanford University, CA

Objective: Our goal is to develop a system leveraging Semantic Web technologies to deliver knowledge to radiologists “just-in-time” as they are interpreting images to help them tackle the challenge of accessing the vast amounts of radiology knowledge. Our system may reduce variation in radiological practice by providing radiologists the knowledge they need.

Methods: We developed an ontological representation of radiological knowledge of focal liver disease diagnosis, encoding the information in two independent knowledge sources (Dahner’s textbook and STATdx from Amirsys Inc.). The model encodes diagnoses, clinical contexts, radiology image features of liver lesions, and probabilistic relationships among entities. We built a computer reasoning application that accesses this knowledge resource (ultimately to be deployed on the Semantic Web), receives

input about the clinical context and image features, and outputs the most likely diagnoses and qualitative probability rankings. We evaluated the system by providing it several cases of known diagnosis.

Results: Our ontological model of radiology successfully captured all the major pieces of information in the knowledge sources. Our decision support application generated a correct differential diagnosis based on observed imaging features in each of the test cases. We are now conducting a study to evaluate the ability of our tool to reduce variation in performance of radiologists interpreting cases of focal liver disease.

Conclusion: We have demonstrated the feasibility of encoding radiological knowledge in a human-readable, machine-accessible ontological form. We also showed the feasibility of using this knowledge to deliver decision support. Our methods may help to improve radiologist diagnostic performance.

An Automated Approach to Analyzing, Reporting, and Communicating Quantitative Imaging

DL Rubin¹, A Snyder¹, M Levy²
¹Department of Radiology, Stanford University, CA; ²Department of Biomedical Informatics, Vanderbilt University, Nashville, TN

Background: A major challenge for quantitative imaging is consistent and reproducible measurement and reporting of cancer lesion measurements over serial imaging. Many different tools to improve lesion measurement and tracking have been developed, but they do not interoperate and thus have not been implemented in clinical practice. We describe an informatics framework that will permit radiologists to “plug together” the various quantitative imaging tools to provide seamless collection, reporting, and communication quantitative imaging studies, focusing on oncology, but generalizable to all of quantitative radiology.

Evaluation: We used the Annotation and Image Markup (AIM) standard of caBIG as the “glue” to tie together different components of quantitative imaging functionality into a cohesive system that automates collection, analysis, and reporting of quantitative imaging studies in cancer. In our framework, the radiologist views the images and annotates the measurable disease in an AIM-compliant workstation (perform linear measure at baseline and each follow up exam). We added a commercial system that consumes the AIM, and uses the radiologist annotations as seed points to automatically segment the lesions and derive additional quantitative measures

such as volume and area. We also created an analytic application that consumes all AIM-encoded image results to provide a graphical summary of the lesions and various quantitative measures (linear dimension, area, volume) over time, providing decision support to the oncologist and a discovery platform to explore novel biomarkers to the clinical researcher.

Discussion: Our exhibit shows how radiologists can plug together AIM-enabled quantitative imaging tools into a powerful platform to streamline quantitative image analysis and reporting. By collecting and exchanging image metadata in AIM, we can automate and improve image-based analysis of disease status and response to treatment. The approach, however, is applicable to all of quantitative radiology.

Conclusion: Tools that save image metadata in standard formats (AIM) can be plugged together to build a powerful system to automate quantitative imaging practice and enable research.

Automatic Extraction of Breast Density Information from Mammography Reports

B Perhcha¹, H Nassif², JA Lipson³, ES Burnside², DL Rubin³
¹Biomedical Informatics Training Program, ³Radiology, Stanford University, CA; ²Department of Radiology, University of Wisconsin Madison, Madison, WI

Purpose: Breast tissue composition is an important risk factor for susceptibility to breast cancer, and information on breast density could play an important role in the development of classification systems for the early and accurate diagnosis of malignancy. Our goal was to develop an automated method to detect and extract the breast density assessments from free-text mammography reports.

Method and Materials: We studied many different mammography reports to understand the variety of ways breast density is reported. We developed an algorithm, based on pattern matching and regular expressions in free text, to automatically detect and extract BI-RADS breast density classes. Using radiologists’ unstructured descriptions of mammograms as its input, the algorithm classifies each report into one of four density classes: fatty (1), fibroglandular

(2), heterogeneously dense (3), or extremely dense (4). We evaluated the algorithm’s performance on a total of 600 reports from two different institutions. Two different radiologists reviewed the reports to establish the gold standard.

Results: The algorithm achieved 100% and 99% classification accuracy on the reports from the two institutions, respectively.

Conclusion: Our automated method to extract breast density composition from unstructured mammography reports has high accuracy in our testing, and appears promising. This method could enable epidemiological research by facilitating data-mining of large-scale data sets to correlate breast density with other covariates.

Image Analysis, Bioinformatics, and Computational Modeling

Automated drusen segmentation and quantitation in SD-OCT images

Q Chen^{1,2}, T Leng³, DL Rubin¹

¹Department of Radiology, ²Byers Eye Institute, Stanford University, CA; ²School of Computer Science and Technology, Nanjing University of Science and Technology, Nanjing, China

Objective: Spectral domain optical coherence tomography (SD-OCT) is a useful tool for the efficient measurement of drusen in patients with age-related macular degeneration (AMD), however, objective assessment of drusen is thwarted by the lack of a method to robustly quantify these lesions on serial OCT images. Here, we describe an automatic drusen segmentation method and quantitative measurement for SD-OCT retinal images.

Methods: Our method leverages a priori knowledge of normal retinal morphology and histological features. The highly reflective and locally connected pixels located below the retinal nerve fiber layer (RNFL) are taken as the initial estimate of the retinal pigment epithelium (RPE) layer location. The potentially abnormal and normal RPE layers are obtained by interpolating and fitting the estimated RPE layer, respectively. The areas located between the fitted normal and interpolated RPE layers are marked as drusen. We also developed a novel method of fundus projection to generate an en face fundus image based on the RPE extraction, which improves the efficiency of drusen visualization over the current approach to producing this projec-

tion based on a summed-voxel projection (SVP), and it provides a means of obtaining quantitative features of drusen in the en face projection. The segmented drusen are refined through several post-processing steps: drusen judgment with consecutive slices, drusen refinement with projection image and drusen smoothing.

Results: In a preliminary analysis, quantitative drusen measurements, such as area and volume, correlate with the drusen progression in non-exudative AMD, suggesting that our approach may produce useful quantitative imaging biomarkers to follow this disease and predict patient outcome.

Conclusion: We have developed a novel automated drusen segmentation algorithm for SD-OCT images, which incorporates the 3D spatial information in retinal structures and information in drusen projection images. The qualitative and quantitative evaluations may be clinically

useful for evaluating the progress of drusen.

Fundus projection image for drusen visualization

Q Chen^{1,2}, T Leng³, DL Rubin¹

¹Department of Radiology, ²Byers Eye Institute, Stanford University, CA; ²School of Computer Science and Technology, Nanjing University of Science and Technology, Nanjing, China

Objective: Three-dimensional optical coherence tomography (3D OCT) produces cross sectional images of the retina, providing detailed display of the shape of sub-retinal abnormalities such as drusen. The purpose is to generate en face fundus image based on 3D OCT images and visualize drusen.

Methods: We describe a novel approach, the improved summed-voxel projection (SVP), to generate en face projection images of the retinal surface. The approach can generate en face fundus images and visualize very small drusen, because the method is enhanced by restricting the projection to the retinal pigment epithelium (RPE) layer neighborhood, and the substance regions of drusen are filled with bright pixels.

Results: Comparative results demonstrate that our method is more effective to display drusen and retinal vessels than conventional SVP.

Conclusion: This paper presents a RPE based projection method for 3D OCT retinal images. By comparing the traditional SVP and two improved projection methods, our method is more effective for the drusen visualization in fundus images, which is important for ophthalmologists to directly and rapidly assess the drusen.

Automated Temporal Tracking and Segmentation of Lymphoma on serial CT Examinations

J Xu¹, H Greenspan³, S Napel^{1,2}, DL Rubin²

Departments of ¹Electrical Engineering, ²Radiology, Stanford University, CA; ³Department of Biomedical Engineering, Tel Aviv University, Tel Aviv, Israel

Purpose: It is challenging to reproducibly measure cancer lesions on numerous follow up studies; the process is time-consuming and error-prone. Our goal was to develop a method to automatically and reproducibly identify and segment abnormal lymph nodes in serial CT exams.

Materials and Methods: Our method leverages radiologist-circumscription of cancerous lymph nodes in the baseline scan. We then identify an approximate region for the node in the follow-up scans using non-rigid image registration. The baseline scan is also used to locate regions of normal, non-nodal tissue surrounding the lymph node and to map them onto the follow-up scans, in order to reduce the search space to locate the lymph node on the follow-up scans. Adaptive region growing and clustering algorithms are then used to obtain the final contours for segmentation. We applied our method to 24 distinct enlarged lymph nodes at 3 or 4 time points from 14 patients. The scan at the earlier time point was used as the baseline scan to be used

in evaluating each follow-up scan, resulting in 70 total test cases (e.g. a series of scans obtained at 4 time points results in 3 test cases). For each of the 70 test cases, a “reference standard” was obtained using manual segmentation by a radiologist. We assessed the performance of our method using Response Evaluation Criteria in Solid Tumors (RECIST), and by calculating node overlap ratio (NOR) and Hausdorff distance (HD) between the computer and radiologist-generated contours.

Results: Compared to the reference standard, our method made the correct RECIST assessment 67/70 (95.7%) times. The average NOR was 80.6% +/- 10.2% s.d., and the average HD was 3.2 mm +/- 1.8 mm s.d.

Conclusion: Our automated method achieves excellent overall segmentation performance and provides equivalent RECIST assessment. It potentially will be useful to streamline and improve cancer lesion measurement and tracking and to improve assessment of cancer treatment response.

Geographic atrophy segmentation for SD-OCT images

Q Chen^{1,2}, T Leng³, DL Rubin¹

¹Department of Radiology, ²Byers Eye Institute, Stanford University, CA; ²School of Computer Science and Technology, Nanjing University of Science and Technology, Nanjing, China

Objective: Age-related macular degeneration (AMD) is a leading cause of irreversible vision loss among the elderly. The advanced form of AMD associated with severe vision loss is characterized by the development of macular neovascularization and geographic atrophy (GA). Automatic quantification of GA is important for determining disease progression and facilitating clinical diagnosis of AMD.

Methods: This paper presents an automatic GA segmentation method for spectral domain optical coherence tomography (SD-OCT) images. Firstly, the retinal pigment epithelium (RPE) layer is estimated according to the reflection property of different retinal layers. Then, three-dimensional (3D) OCT images are transformed to 2D fundus projection images by restricting the projection to the region underneath the RPE layer. Finally, an adaptive edge-based level set method is adopted to segment the GA based on the projection image.

Results: Experimental results demonstrate that the proposed method is effective for the GA segmentation. The segmentation accuracy is approximately 97%.

Conclusion: We have developed a novel automated GA segmentation algorithm for SD-OCT images, which transforms the 3D OCT image segmentation into 2D fundus projection image segmentation. The quantitative evaluations indicate that our method can achieve high segmentation accuracy.

Image Analysis, Bioinformatics, and Computational Modeling

Lesion Classification using Dictionary of Words Approach

R Pasari¹, H Greenspan², DL Rubin¹

¹Department of Radiology, Stanford University, CA; ²IBM Almaden Research Laboratories

PURPOSE: A challenge in developing automated image analysis for diagnosis in radiology is variation in appearances of disease. Our goal was to develop a method for automated lesion diagnosis that learns from actual case data by leveraging image patch methodology.

METHOD AND MATERIALS: We obtained 73 CT images of liver lesions (25 cysts, 24 metastasis and 24 hemangiomas). A radiologist circumscribed each lesion, and we extracted uniform-sized patches such that the entire lesion and its margins were included. We extracted features in the patches using principal components analysis, selected of the highest energy components, and clustered them to build a “visual dictionary” where the cluster centroids represent the distinct “words” in the images. We built a feature vector for each image that records the fraction of its patches that are closest to each cluster centroid (length of the vector is the number of cluster centroids). These feature vectors were used to train a multi-class SVM classifier (LibSVM) to predict the diagnosis for each image. We used leave-one-out cross-validation to measure

Figure shows regions of lesion from which image patches are derived (left) and the patches themselves (right). Patches are derived by centering them on pixels within the substance of the lesion (yellow) and in proximity to the boundary of the lesion (red).

the accuracy. We optimized the number of PCA components, clusters in K-means, and size of a patch. We created separate dictionaries for the interior and for the boundary of a lesion to improve system performance.

RESULTS: Our method predicted the correct diagnosis for the lesions with an accuracy of 95%. The few errors in classification which occurred are due to the hemangioma being confused as metastasis. The benefit of the image patch-based method is that it uses the raw image itself as features, and its performance may generalize beyond the three types of lesions tested in this study.

CONCLUSION: We developed an automated method to analyze and classify three types of focal liver lesions based on image patches and a visual dictionary of words derived from them. The classification accuracy appears promising, and the results may generalize to a wider range of lesion diagnoses as we accrue a larger database of liver lesions.

Lesion Detection using Dictionary of Words Approach

R Pasari¹, H Greenspan², DL Rubin¹

¹Department of Radiology, Stanford University, CA; ²IBM Almaden Research Laboratories

PURPOSE: Our goal was to develop an automated tool which can detect and segment lesions in a liver CT scan image.

METHOD AND MATERIALS: We obtained 73 CT images of liver lesions. A radiologist circumscribed one lesion in each image. Also we had the radiologist mark areas of normal liver in the images. We extracted image patches from the lesion and normal liver and we performed PCA analysis on them and clustered the results using k-means clustering. Then we built a feature vector for each image of lesion and normal liver that records the fraction of its patches that are closest to each cluster centroid (length of the vector is the number of cluster centroids). These feature vectors were used to train a binary SVM classifier (LibSVM) to predict le-

Image of a lesion where the window is divided into sub-windows and each sub-window classified as either lesion (yellow box) or normal liver (red box).

sion or normal liver. Then given a query image we divide it into sub-windows and classify each sub-window as either normal liver or lesion.

RESULTS: Lesion detection using this dictionary based approach is giving very good preliminary results without using any post processing. It is mostly correctly identifying the lesions. However, the method also identifies the liver boundary as lesion. This is a case of false positives and will reduce our precision.

CONCLUSION: We developed an automated method to segment lesions from a liver image using image patches and a visual dictionary of words derived from them. The results appear promising and the case of false positives described above can be tackled by using some liver segmentation algorithm which demarcates the margin of the liver.

Extension and Application of RadLex to Annotation of Neuroimaging Data

J Turner¹, JV Mejino², T Detwiler², M Martone³, J Brinkley², DL Rubin⁴

¹The MIND Research Network, Phoenix, AZ; ²Department of Biological Structure, University of Washington, WA; ³Department of Neurosciences, UC San Diego, CA; ⁴Department of Radiology, Stanford University, CA

PURPOSE: There are several different terminologies available for annotating functional neuroimaging results to enable data sharing and reuse. Our goal was to address this challenge by harmonizing the major neuroanatomy terminologies which we then incorporated into RadLex, a standard ontology for radiology.

METHOD AND MATERIALS: We used a reference ontology, the Foundational Model of Anatomy Ontology (FMA), to include and correlate information on cytoarchitectonics (Brodmann area labels), and morphological cortical ontologic schemes (e.g., the part of Brodmann area 6 located in the left precentral gyrus) that are represented in the different terminologies. This representation was used to augment the neuroanatomical axis of RadLex, the ontology for clinical imaging. To evaluate our work, we annotated a large functional neuroimaging dataset with terms from the expanded RadLex ontology. We applied a reasoning engine to the annotated images to analyze them in conjunction with the ontology to answer the research questions associated with this dataset.

RESULTS: Our neuroanatomy ontology declares the explicit representation of structural relationships such as parthood and connectivity between neuroanatomical entities which allows for relating ontologically the neuroanatomical entities referenced by the different labeling schemas. This therefore provides RadLex an ontology that can harmonize and unify image datasets that are annotated with disparate neuroanatomical terminologies. The analyses we performed on the RadLex-annotated images achieved successful inferences from the most granular level (e.g., how many subjects showed activation in a sub-part of the middle frontal gyrus) to the most general level (e.g., how many activation sites were found in either right or left frontal cortex).

CONCLUSION: We have augmented RadLex to harmonize the major terminologies and cortical parcellation schemes used in neuroimaging. Our work can be exploited by computer reasoning engines to make inferences about neuroanatomical relationships in imaging datasets that use the different terminologies, and could enable knowledge discovery from large distributed fMRI studies.

High-throughput multiple mouse imaging on MicroPET and MicroPET-CT scanners: Effect on Quantitation

F Habte^{1,2}, G Ren^{1,2}, TC Doyle^{1,3}, Z Cheng^{1,2}, D Paik^{1,2}

Departments of ²Radiology, ¹MIPS, ³Pediatrics, Stanford University, CA

Small animal microPET imaging is becoming an increasingly important modality, currently commonly used in the development of novel imaging agents, drug treatments and animal disease models. This increased demand has lead the use of a three- or four-mouse “hotel” to simultaneously image multiple anesthetized animals. This significantly reduces the scan time, while also allowing experiments to be designed with significantly larger cohorts of animals, as well as decreasing the data processing time, storage requirements and post-acquisition analysis required. In this study, we assessed the quantitative impact of scanning four animals, relative to single animals on a multi-modality MicroPET-CT scanner and on a dedicated MicroPET scanner. Mice were injected with a ⁶⁴Cu-labeled radiotracer (with a relatively long half-life to minimize decay variance between imaging studies), and then sequentially scanned either in a four-mouse “hotel” or individually on both MicroPET-CT and MicroPET scanners. For validation purposes, we also scanned cylindrical phantoms using both single and multiple animal techniques. A semi-automatic threshold-based Region

of Interest (ROI) tool was used to minimize operator variability during image analysis. Ex vivo bio-distribution studies were performed on all animals as a gold standard to compare with image quantitation. Our results indicate that there is minimal difference in the quantification of radionuclide uptake in selected major organs between conventional single mouse scans and multi-animal scans in our mouse “hotel” on either the MicroPET or MicroPET-CT scanners. We obtained less than 7% relative error difference with respect to %ID/gram between the multi-mouse and single mouse scans, and a 4% relative error

difference with the cylinder phantom studies. These results confirmed that there is little no significant difference in uptake quantification of small animal PET images compared to the near 20% variability seen in repeat scans, and that use of the mouse “hotel” is a valid aid to increasing instrument throughput on small animal scanners.

Left: Four animal “hotel” setup illustrating high throughput multi-animal scanning on microPET to decrease scan time while decreasing data storage and processing demands. Right: Corresponding volume rendered microPET/CT data.

Narrow Peak Spectral Algorithm: Improved Method for Unmixing of Raman Labeled Nanoparticles

K Kode^{1,3}, C Shachaf^{1,2}, S Elchuri², G Nolan², DS Paik¹
Departments of ¹Radiology, ²Microbiology and Immunology, ³Computational and Mathematical Engineering, Stanford University, CA

Raman spectroscopy can differentiate the spectral fingerprints of many molecules, resulting in potentially high multiplexing capabilities of Raman-tagged nanoparticles. However, accurate quantitative unmixing of Raman spectra is challenging because of potential overlaps between Raman peaks from each molecule as well as slight variations in the location, height and width of the very narrow peaks. If not accounted for, even minor fluctuations in the spectra may produce significant error which will ultimately result in poor unmixing accuracy. We developed and evaluated an algorithm named Narrow Peak Spectral Algorithm (NPSA) for unmixing the contributions from each nanoparticle allowing simultaneous quantitation of several nanoparticle concentrations during sample characterization. The Carbon Organic-inorganic Nanoparticles (COINs) used in this study were prepared by reduction of silver nitrate with sodium borohydride and then were aggregated with organic Raman labels in the presence of sodium chloride. The COINs were then encapsulated with bovine serum and cross-linked with glutaraldehyde.

Using NPSA, we were able to successfully unmix Raman spectra from up to 7 Raman nanoparticles after correcting for the spectral variations of 30% in intensity and shifts in peak locations of up to 10 cm-1 which is equivalent to 50% of the full width at half maximum (FWHM). We compared the performance of NPSA to the conventional least squares analysis (LS), error in NPSA is approximately 50% lower than LS. The error in estimating the relative contributions of each nanoparticle using NPSA are in the range of 10-19% for unmixing of 7 COINs whereas the errors using the traditional least squares approach were in the range of 25-68%. Our results demonstrate that accounting for variability in the spectra can lead to better and more reliable performance in quantitative unmixing thereby enabling Raman spectroscopic imaging in living subjects.

Characterization of Variability across SERS spectra of Raman Labeled Nanoparticles

K Kode^{1,3}, C Shachaf^{1,2}, S Elchuri², G Nolan², DS Paik¹
Departments of ¹Radiology, ²Microbiology and Immunology, ³Computational and Mathematical Engineering, Stanford University, CA.

The potential of Raman spectroscopy in multiplexing of Raman-tagged nanoparticles which is crucial in immuno-detection is limited by the variability associated with the SERS spectra of these nanoparticles. If not accounted for properly, even minor fluctuations in the spectra may produce significant error which will ultimately result in poor unmixing accuracy. The objective of our study was to characterize the variability across SERS spectra of different Carbon Organic-inorganic Nanoparticles (COINs). To study the variability in the SERS spectra of different COINs, spectra were collected from 289 (17x17) spots for each sample. A peak detection algorithm was developed to extract features from each spectra. The approximate peak location, height and full width at half maximum (FWHM) of the Raman peaks obtained from peak detection algorithm were refined by fitting Gaussian functions to the peaks using an optimization routine. The variation in center location of peaks was quite significant in some of the spectra with the peaks being shifted by as much as 14 cm-1 with re-

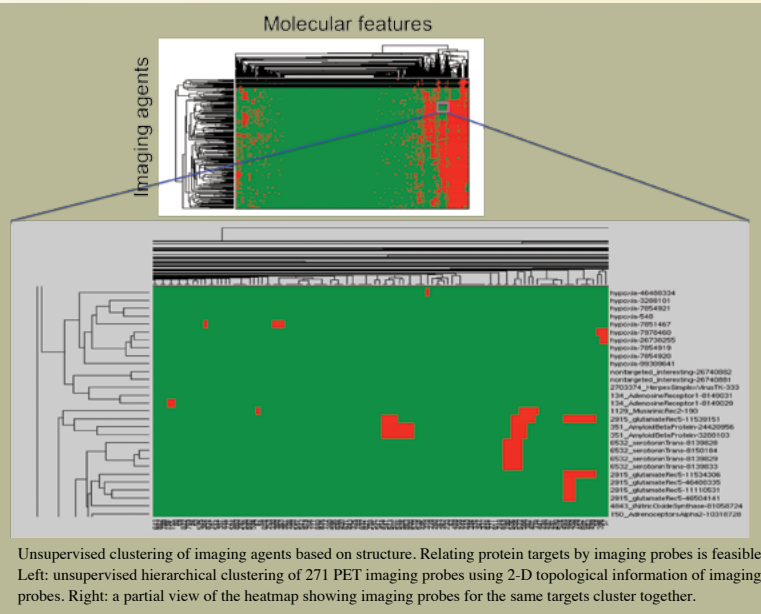

spect to the mean location. Similarly, variations in the peak intensity as well as FWHM were significant enough to render quantitative unmixing erroneous. Also, the variations observed in different peaks of the spectra were highly uncorrelated suggesting that each peak should be corrected for independently. While the narrow peaks of the Raman spectra provide specificity of each nanoparticle's spectrum, their steep slopes can lead to large errors in the presence of very minor spectral shifts or changes in width. Our results demonstrated that the SERS spectra of COINs have significant variation and accounting for this is necessary to achieve reliable performance in quantitative unmixing thereby enabling Raman spectroscopic imaging in living subjects. We developed an efficient unmixing algorithm that accounts for the observed variability which is discussed in our Lucas report 'Narrow Peak Spectral Algorithm: Improved Method for Unmixing of Raman Labeled Nanoparticles'.

A systems approach to characterize molecular targets for imaging agents

TT Liu^{1,2}, D Paik^{1,2}
Departments of ¹Radiology, MIPS, ISIS, ²Biomedical Informatics, Stanford University, CA

The development of novel imaging agents and the identification of their molecular targets are areas of intense research and have a wide range of applications in both biomedical research and in clinic. Here we show we can use a computational approach to characterizing the molecular target of an imaging agent. We hierarchically clustered targets based on the molecular features of their corresponding imaging agents. Although previous studies have applied and validated this approach on pharmacological data, to our knowledge, this is the first study that this approach is applied to imaging agent data. Our dataset consists of 400 small molecular imaging agents annotated into sets for over 80 protein targets. First, we demonstrated the feasibility of this computational approach on imaging agents by performing unsupervised clustering based on topology of imaging agents.

Our result shows that imaging agents for the same biological target cluster together based on chemical structure features. We calculated a pairwise similarity score between every two sets of imaging agents. The similarity scores were expressed in a network with nodes being the targets. We further tested the model on an external set of EGFR imaging agents, and EGFR was returned as the top hit of a ranked list of molecular protein targets. Although experimental validation is needed, this systems approach to molecular imaging agents across multiple targets is effective for characterization and identification molecular targets for imaging agents.

The Imaging Biomarker Ontology: ontology-based support for imaging biomarker research

TT Liu^{1,2}, E Savig³, DL Rubin^{1,2}, D Paik^{1,2}
Departments of ¹Radiology, MIPS, ISIS, ²Biomedical Informatics, ³Cancer Biology Program, Stanford University, CA

The purpose of this project is to develop an ontology to represent and integrate the heterogeneous knowledge in the domain of imaging biomarkers, for the purpose of enabling the storage and retrieval of desired imaging biomarker measurements, mining the expanding imaging literature, and discovery of novel imaging biomarkers. We have developed the Imaging Biomarker Ontology to support imaging biomarker research. It integrates heterogeneous knowledge in the field of imaging biomarker research, and bridges pre-clinical and clinical imaging biomarker research. The Imaging Biomarker Ontology we have developed integrates knowledge in different fields represented by 9 upper classes, including image technique (imaging agent, imaging instrument), method of quantitation (image processing and analysis algorithm), and biology of interest (biologi-

cal target, indicated biology, and biomarker application). The ontology also includes both clinical terms (e.g. DISEASE) and terms used in basic biological research (e.g. BIOLOGICAL PROCESS). Integration of these different fields will facilitate biomarker discovery and accelerate translation of imaging biomarker from research to clinical use. In addition, we reuse existing ontologies whenever possible. To our knowledge, this is the first ontological representation of knowledge in imaging biomarker research. The complete Imaging Biomarker Ontology will soon be made available to the public domain. Following the ontology development, we will validate the ontology using published imaging biomarker data and demonstrate its utility in various applications, such as data retrieval, mining new information from the literature, and discovering novel imaging biomarkers.

Software Only Method for QC of Monitor Quality and Reading Conditions in Multisite Image Reading Trials

D Rasooly, F Schmitzberger, TJ Kim, M Tall, J Roos, S Napel, G Rubin, D Paik
Department of Radiology, Stanford University, CA

Purpose: Quality control (QC) of display monitors and reading environment in a multisite image reading trial is difficult to maintain. We have validated a simple psychoperceptual software-only test that eliminates the need to send a photometer to each site for QC.

Methods: Characteristic luminance curves were measured using a photometer on 24 displays (18 LCD, 6 CRT). 6 readers incremented grayscale intensity differences (ΔI) between text and background until able to correctly read a 4 digit code in an 8-bit image on white, gray, and black backgrounds. Tests were done with indoor lighting both on and off, with the controls done in a closed office (no windows) and the experimental measurements in a suboptimal, non-clinical reading environment (windows with significant ambient light). As a gold standard of reader contrast detectability, just noticeable difference in contrast (C_{JND}) was calculated. Acceptable performance under the various lighting conditions was set at $C_{JND} < 7.5\%$.

Results: ΔI scores obtained with indoor lighting were on average 0.08-0.86 grayscale units higher than corresponding ΔI scores obtained with no ambient

lighting, indicating that ambient light has minimal influence on perceptual ability compared to inter-reader variability. Of the 18 different monitor and monitor setting tested, 9 had maximum luminance values less than 173 cd/m², the AAPM recommended minimum value. ΔI scores obtained from the 9 monitors below the 173 cd/m² threshold averaged at 6.5-10.6 grayscale units, while those over the threshold averaged at 7.6-11.4 grayscale units leading to a difference of 0.1-1.1 grayscale units between the two groups, indicating that poor monitor luminance also has minimal influence on perceptual ability. Out of 256 grayscale values on a typical 8-bit display of window-leveled images, these differences in grayscale perception are minimal and in fact, well below inter-reader variation.

Conclusion: Somewhat counter-intuitively, ambient lighting and poor monitor quality have minimal influence on perceptual ability, especially when compared to inter-reader variability. This effect can be modeled using either the Weber-Fechner law of perception or the DICOM Grayscale Standard Display Function (GSDF).

A Computational Representation of Nanoparticle Structure to Enable Structure-Based Queries of Nanomedicine Resources

C Nwabugwu^{1,2}, K Kode^{1,3}, S Gaheen⁴, N Baker⁵, D Paik¹
Departments of ¹Radiology, ²Electrical Engineering, ³CME, Stanford University, CA; ⁴National Institutes of Health; ⁵Pacific Northwest National Laboratory

The data being generated from experiments in cancer nanotechnology research—an intrinsically interdisciplinary research field devoted to the development and application of nanotechnology-based methods in the treatment, diagnosis and detection of cancer—is growing at an exponential pace. It is vital to keep up with the flood of new information about the biological properties of nanoparticles used for both imaging and therapy. We are devising a method for graphically specifying database queries based on the structure of nanoparticles. This includes developing a computational representation of the modular structure of engineered nanoparticles.

The NanoParticle Ontology (NPO) is an ontology—a formal, explicit representation of knowledge belonging to a subject area—which has been developed within the framework of the Basic Formal Ontology (BFO), and implemented in the Ontology Web Language (OWL) using established ontology design principles. It was developed to represent knowledge underlying the preparation, chemical composition, and characterization of

nanomaterials involved in cancer research. nano-TAB is a tab-delimited spreadsheet type of format facilitating the submission and exchange of data pertaining to nanomaterials and their characterizations (physico-chemical, in vitro, and in vivo). It is based on existing standards developed by the European Bioinformatics Institute (EBI) and the Investigation/Study/Assay (ISA-TAB) file format, which represents a variety of assays and technology types. The nano-TAB specification leverages ISA-TAB files describing investigations, studies, and assays and provides extensions to support nanomaterial structural information and concepts on nanotechnology assay measurements defined in the NPO. We have developed and object-oriented design for representing nano-TAB materials files using the Java programming language and we are currently implementing a graphical user interface for creating these files from a palette of nanostructures. Future work will involve creating a similarity metric for nanoparticle structures, searching multiple online resources and eventually using this tool for novel nanoparticle design.

Figure 1. The G4 tris(hydroxyl) terminated PAMAM dendrimer structure and its corresponding nano-TAB material file. Structure comes from caNanoLab NCL-20 (Hall, et al).

A Gold Standard for Visual Similarity of Lesions on CT Liver Images: Inter-reader Variability

JS Faruque¹, DL Rubin², CF Beaulieu², J Rosenberg², RM Summers³, A Kamaya², G Tye², S Napel²
Departments of ¹Electrical Engineering, ²Radiology, Stanford University, CA; ³National Institutes of Health Clinical Research Center, Bethesda, MD

Purpose: We are creating a perceptual gold standard for visual similarity in medical images that may be used for training and validating a content-based image retrieval system. In this study, we evaluated inter-reader variability when assessing visual similarity of liver lesions seen at portal venous CT.

Methods and Materials: We displayed 19 portal venous CT images containing liver lesions individually (phase 1) and in all 171 pair-wise combinations (phase 2) to 3 radiologists in random order. For phase 1, each image was rated for 6 visual attributes ((1) number of different compartments and (2) densities, (3) average density, (4) margin definition and (5) contour, and (6) rim density) on a 9-point scale. For phase 2, each pair of images was rated for similarity in the same 6 attributes as well as for overall similarity. We calculated inter-reader variability between each set of ratings and each pair of readers using the Cohen’s Kappa metric.

(a) Images used for this study; red box surrounds lesion in question. Example (b) histograms and (c) Cohen’s Kappa scores for Phase 2 ratings of the similarity of average density between image pairs.

Results: For Phase 1, the Kappa scores ranged from 0.49-0.53, 0.29-0.73, 0.88-0.92, 0.61-0.67, 0.56-0.64, and 0.41-0.79 for attributes (1) through (6), respectively. For Phase 2, the Kappa scores ranged from 0.29-0.54, 0.39-0.51, 0.73-0.78, 0.47-0.54, 0.38-0.62, 0.29-0.39, and 0.42-0.72 for attributes (1) through (6) and overall similarity, respectively.

Conclusion: Inter-reader agreement varied in a wide range depending on attributes. Inter-reader agreement is better when rating attributes of single images as opposed to rating similarity (attribute-wise or overall) between pairs. The attributes of Average Density, Margin Definition, and Margin Contour had greater inter-reader agreement and may thus be more valuable when creating a reference standard.

Prediction of radiologist observations using computational image features

F Gimenez¹, J Xu², Y Liu¹, T Liu¹, CF Beaulieu³, DL Rubin³, S Napel³
Departments of ¹Medicine (Biomedical Informatics Research), ²Electrical Engineering, ³Radiology, Stanford University, CA

PURPOSE: We propose that radiological annotations can be predicted using quantitative features derived from image data.

METHOD AND MATERIALS: We utilized 79 portal-venous phase CT studies containing liver lesions. A radiologist selected a representative slice from each study, circumscribed the lesion, and annotated it using a controlled vocabulary of 76 terms. The annotations were performed using OsiriX and the Electronic Physician’s Annotation Device (ePad) plug-in. Annotations were concatenated into a binary feature vector referred to as the “semantic features.” Computationally derived features were then extracted from the images that describe lesion intensity, texture, shape, and edge sharpness of lesions. These features were used to train a logistic regression classifier with L1-regularization to predict each semantic feature. Leave-one-out cross-validation was used to calculate the probability of a feature’s presence given the computationally-derived features. These probabilities were used to create receiver operating characteristic (ROC) curves. Area under the curve, optimal classification threshold, and misclassification rate

were computed to analyze the effectiveness of classification.

RESULTS: The AUC for the semantic features indicated good performance (mean 0.82 +/- 0.14). The mean misclassification rate using the optimal classification thresholds was 0.14 +/- 0.09. Several annotations were predicted particularly well, including water density, homogeneous retention, non-enhancing, heterogeneous, and homogenous, all of which had an AUC over 0.95. A few semantic features were difficult to predict, including normal perilesional tissue, round, and ovoid (AUC < 0.6).

CONCLUSION: We used a statistical machine learning classifier to predict radiological annotations of liver lesions using computationally derived quantitative imaging features. Results showed that prediction of such features is feasible and may potentially be used in conjunction with radiologists to verify their observations in real-time. Further work may be done to extract more relevant image features, to improve classification accuracy, and to verify this system using a larger data set.

Image Analysis, Bioinformatics, and Computational Modeling

Quantitative analysis of 4-d gaze tracks through lung CT data during nodule search

K Roychoudhury¹, M Tall¹, JE Roos³, GD Rubin¹, S Napel²
Departments of ¹Radiology, Duke University, NC; ²Radiology, Stanford University, CA; ³Radiology, University Hospital Zurich, Switzerland

PURPOSE: Gaze tracking is a promising tool to enhance our understanding of the search for and detection of lung nodules. We have developed a platform for recording four-dimensional (x, y, z, t) gaze data while radiologists search and identify lung nodules in CT scans. Our goal is to develop an analysis of these data that characterizes the relationship between the gaze path and nodule detection.

METHOD AND MATERIALS: Two radiologists performed unrestricted search on sets of contiguous transverse sections from 38 lung CT scans implanted with between 3 and 6 simulated nodules per scan. The gaze path over the computer display (x, y, t) was associated with variations in longitudinal position (z, t) controlled by the readers using a computer mouse. The speed of eye movement was estimated from smoothed time derivatives of x and y movement obtained using a short window smoothing spline. Locations of rapid eye movement (saccades) were estimated by applying a speed threshold. Saccadic epochs (time intervals) were identified using a zero crossing algorithm applied to the speed function. Fixation (dwell time) epochs are identified

as complementary to saccadic ones. Variations in saccadic and fixation durations were identified using analysis of variance (ANOVA).

RESULTS: Spatial analysis revealed significant differences in scanning patterns for the same task across readers. Typically movement in the Z direction is much slower than in the XY plane, hence Z movement did not contribute to the identification of transient features like saccades. The saccade identification algorithm was validated across different readers and cases. For nodule detection, median durations were 0.12 seconds for saccades and 0.55 seconds for fixations, but with significant differences across readers. The distributions of saccades and fixations are positively skewed but can be approximately normalized using a log transform.

CONCLUSION: The recording and subsequent analysis of four dimensional gaze paths during lung CT interpretation reveal unique aspects of radiologist's search strategies, thus offering the potential for directing readers toward improved accuracy and consistency of performance when searching for lung nodules.

Annotation and integration of CT and PET images with gene expression in NSCLC for decision support and discovery

S Napel¹, CD Hoang², J Xu³, O Gevaert¹, DL Rubin¹, Y Xu², ANC Leung¹, A Quon¹, SK Plevritis¹
Departments of ¹Radiology, ²Cardiothoracic Surgery, ³Electrical Engineering, Stanford University, CA

PURPOSE: Use of images for data-driven discovery and decision support requires their annotation with machine accessible features. We show methods and preliminary results in 26 NSCLC patients (18 male; 8 female; aged 50-86, mean 68) who had imaging and gene expression microarrays of the excised tumor.

METHOD AND MATERIALS: CT parameters: slice thickness ≤ 1.5 mm, 120 kVP, tube current 100-700 mA, pitch 0.9-1.0. FDG-PET/CT parameters: FDG 10-17 mCi (.21 mCi/kg), slice thicknesses 3.75-5 mm. We annotated an NSCLC nodule in each CT study by choosing from among 71 controlled terms from each of 19 categories (e.g., location, density, calcification status) and in each PET scan using SUV. We also computed 153 pixel-based features (e.g., Gabor texture, margin sharpness and shape) of the nodule in the CT scans. We processed gene expression from Illumina Whole Genome Bead Chips (Human HT-12) by k-means clustering into 56 co-expressed clusters. We performed univariate and multivariate analyses to integrate image features and metagenes using Significance Analysis of Microarrays, and sparse linear regression, respectively.

RESULTS: We observed diverse features in this small cohort: 31% of the semantic and 39% of the computational features have entropy > 0.8 and variance $> 10\%$, respectively. Univariate analysis found 243 significant associations between image features and metagenes; e.g., a metagene implicated in focal and cell adhesion, extracellular matrix receptor interaction, and TGF-beta signaling pathways was associated with image features indicating pleural and blood vessel displacement towards the tumor. Multivariate analysis showed that all 56 metagenes could be modeled by the image features with a mean accuracy of 72% (59%-83%), and that the top 10 predicted computational image features (predominately associated with lesion size, edge shape and edge sharpness), could be predicted with an average accuracy of 85%.

CONCLUSION: It is possible to derive a machine-accessible image phenotype based on semantic and pixel-based features, which can in turn be linked to molecular features. Continued evaluation in a larger database is warranted.

Developing Image Features for Characterizing Non-small Cell Lung Cancer

J Xu¹, CD Hoang², ANC Leung³, A Quon³, DL Rubin³, O Gevaert³, SK Plevritis³, S Napel³
Departments of ¹Electrical Engineering, ²Cardiothoracic Surgery, ³Radiology, Stanford University, CA

Purpose: The ability to use images for data-driven discovery and decision support requires their annotation with machine accessible features. Accordingly, we aim to accomplish this for Non-small Cell Lung Cancer (NSCLC), and have begun with a database of 26 patients who each had a thin-section CT as well as a PET study.

Materials and Methods: For each case, a thoracic radiologist identified and annotated a pulmonary nodule in the CT study using a controlled vocabulary of 71 semantic terms, a nuclear medicine physician determined the Standard Uptake Value (SUV) from the PET scan, and we applied computer algorithms to the nodule area identified in the CT scans to extract pixel-based imaging features. Each nodule was represented by a 178-element feature vector composed of 71-element binary semantic descriptor, 1-element SUV, and a 106-element computational feature

A Software Framework for Extracting Computational Imaging Features from Medical Imaging Data

J Xu¹, CF Beaulieu², DL Rubin², S Napel²
Departments of ¹Electrical Engineering, ²Radiology, Stanford University, CA

Purpose: We are in the process of building large databases linking image features to other data, e.g., clinical, gene expression, pathology. To this end, we are developing a software platform for rapid and complete characterization of imaging features from medical imaging data.

Materials and Methods: Regions of interest (ROI) in representative cross-sections of volumetric imaging data were defined and stored in a set of XML-format Annotation and Image Markup (AIM) files, along with pointers to the relevant DICOM image files. In addition to the coordinates of the ROIs, each AIM file contained semantic annotations, described by radiologists. To this semantic description of the each ROI, our software added pixel-based features computed from pixels within the ROI, resulting in rich feature vectors describing each image in the database.

Visualization cross-sections through all lung nodules in a set of 58 lung CT images. ROI for each image is shown in red.

pression, may reveal molecular characteristics underlying medical image features and find use as markers for molecularly-targeted therapeutics.

This MRI section will explore and highlight new and novel accomplishments made over the last year in the critical areas of MRI instrumentation and applications. These new advances provide improved capabilities to detect pathologies in clinical applications as well as to inform basic science understanding of the human body’s physiology, function, and biology.

MR-guided High Intensity Focused Ultrasound for Pre-surgical Localization of Occult Breast Tumors

R Bitton¹, E Kaye², F Dirbas³, B Daniel¹, K Butts-Pauly¹
Departments of ¹Radiology, ²Electrical Engineering, ³Surgery, Stanford University, CA

Breast conservation surgery (BCS) has become a standard of care as an accepted alternative to mastectomy in patients suffering from limited stage breast cancer 1. Non-palpable tumors present a challenge for surgeons, as palpability often locates the tumor in the breast. The most clinically accepted standard is image-guided single needle wire localization2. Wire localization has several downsides, including wire dislocation between placement and surgery, wire entry site conflicting with ideal surgical site, and the inability to delineate non-palpable tumor boundaries of irregular shape3. As an alternative to wire localization, we propose using MR-guided High Intensity Focused Ultrasound (MR-HIFU) to create thermal lesions that circumscribe a non-palpable breast tumor, providing an excision guide during breast conservation surgery. We use an elastography technique called MR Acoustic Radiation Force Imaging (MR-ARFI) to “remotely palpate” ablations and test lesion stiffness in ex vivo cadaveric breast.

MR-HIFU ablations spaced 5mm apart were made in 18 locations using the ExAb-late2000® system. Ablations were formed a square perimeter in mixed adipose and fibroglandular tissue. Ablation was monitored using T1wFSE images. MR-

a) MR-HIFU fat saturated planning image in cadaveric breast. Green circles indicate 18 planned ablation lesions representing a tumor boundary. b,c) Treatment monitoring during breast tissue ablation. T1wFSE images b) before ablation with US off and c) during ablation with US on, showing the location of the focal spot. d)* Indicates MR-ARFI remote palpation. MR-ARFI phase maps show baseline displacement before MR-HIFU ablation (left), and after ablation (right). e) MR-ARFI displacement profiles (mean ± std) where post ablation profiles (red) show a reduction in tissue displacement, indicating increase in tissue stiffness.

ARFI was used to remotely palpate each ablation location, measuring tissue displacement before and after thermal sonications. Profiles centered at each ablation spot were plotted for comparison. The cadaveric breast was manually palpated to assess stiffness of ablated lesions and dissected for gross examination. This study was repeated on three cadaveric breasts.

MR-ARFI showed a collective post ablation reduction in displacement of 54.8%, indicating the tissue became stiffer after the ablation. Manual palpation and dissection of the breast confirmed increased palpability, a darkening of ablation perimeter, and individual ablations visible in fibroglandular tissue.

The results of this preliminary study show MR-HIFU has the ability to create palpable lesions in ex vivo cadaveric breast tissue, and may potentially be used to pre-operatively localize non-palpable breast tumors.

Real Time Respiration Based Steering for High Intensity Focused Ultrasound in the Liver

AB Holbrook¹, C Dumoulin, JM Santos, Y Medan, K Butts-Pauly¹
Department of ¹Radiology, RSL, ²Bioengineering, Stanford University, CA; ³Department of Radiology, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; ⁴HeartVista, Inc, Palo Alto, CA; ⁵InSightec, Ltd, Tirat Carmel, Israel

Free breathing HIFU liver treatment requires maintenance of the target focus, requiring tracking of both target and transducer. We developed an MR-guided system for guiding liver ablation, with key elements being target tracking and steering through correlation with respiratory bellows and temperature monitoring. The purpose of this work was quantifying steering accuracy with this approach. A phantom was immersed in water and placed above a fixed phased-array transducer. The setup was positioned inside a 3T scanner. A servo-motor moved the phantom sinusoidally, with an attached respiratory belt measuring motion. The phantom’s edge was marked on pre-heating images and tracked throughout motion, and built-in tracking

Representative images of unsteered (top row), steered (middle row), and static (bottom row) HIFU ablations in a phantom. Note that the steered ablations very closely resemble the static examples.

steered ablations were very similar to static ablations.

Fabrication of CMUT 2D arrays using Thick-BOX process for HIFU liver ablation

HS Yoon¹, S Vaithilingam¹, F Sarioglu¹, M Kupnik¹, K Butts-Pauly², BT Khuri-Yakub¹
Departments of ¹Electrical Engineering, ²Radiology, Stanford University, CA

Recently, we have developed capacitive micromachined ultrasonic transducer (CMUT) for high intensity focused ultrasound (HIFU) liver ablation. To meet the challenging demands of the large area arrays, we are using a new fabrication process named “Thick-BOX process” as it allows the top silicon surface to be ground resulting in good shielding for human safety and better signal quality. The “Thick BOX” layer in the substrate wafer is a robust cell structure with immunity to breakdown voltage. Starting with SOI wafer, 0.4-μm of gap height is defined using double oxidation method. Deep trenches around the gap are then etched down to the BOX layer to isolate the center silicon electrode. 0.4-μm of thermal oxide is grown as an insulation layer, followed by direct wafer bonding using chemical surface activation. For

Electrical impedance of sample device

the backside electrical access, via holes are etched from the backside and filled with poly silicon. Under bump metallization is stacked with Al, Ti, Ni and Au, then electrically isolated by trenches on the backside. Handle layer is removed by isotropic dry etching also by wet etching for oxide layer. Top exposed plate is patterned and etched to connect the top plate to the ground. Finally, thin aluminum layer is evaporated with 45 ° angle to connect the sidewalls of the top silicon plate of the ground cells. Electrical impedance is measured with 1mm single-element transducers, resonant frequency are around 2.5 MHz 3 MHz in air. As next tasks, the small transducers will be tiled to 2D arrays, tuned with inductors and output pressure will be measured in immersion.

Measuring temperature rise during spin echo MR-ARFI acquisition

E Kaye^{1,2}, K Butts-Pauly²
Departments of ¹Electrical Engineering, ²Radiology, RSL, Stanford University, CA

MR-guided Focused Ultrasound (FUS) is a promising minimally invasive treatment for various pathologies [1-2]. During the targeting stage of the treatment, the transducer is calibrated to insure the accurate position of the focal spot based on small temperature rise sonications, and visualized with MR using PRF thermometry. MR Acoustic Radiation Force Imaging (MR-ARFI) has been recently demonstrated [3-4] as an alternative tool for focal spot localization that is not expected to produce a temperature rise. To ensure safe use of such sequences in this work we show how temperature and displacement can be monitored simultaneously using a modified spin echo MR-ARFI pulse sequence (Figure 1).

A spin echo MR-ARFI pulse sequence was modified to acquire a gradient echo after 90° RF pulse. The sequence was tested in ex vivo porcine brain tissue using a planar FUS transducer. The duration of the FUS pulse was 18 ms. The acoustic power was varied from 37W to 185W in step of 18W and at each power level a temperature map and a displacement map were acquired simultaneously using a 3T GE MRI scanner. GRE TE was 10 ms and SE TE was 47 ms.

The temperature and displacement images are shown in Figure 2. The mean temperature and mean displacement calculated in the 4 pixel region of interest in the center of focal spot are plotted as a function of power. Both quantities linearly increase with power. The results show that 1 to 2 degree temperature rise is anticipated for the lowest acoustic power necessary to produce measurable displacement. This temperature rise should be negligible in perfused tissue, however, if the MR-ARFI is going to be performed repeatedly, temperature monitoring could be still beneficial.

Real-time Monitoring of Tissue ADC During High Intensity Ultrasound Ablation of the Prostate

J Plata¹, A Holbrook¹, P Prakash², V Salgaonkar², P Jones², C Diederich², G Sommer¹, K Butts-Pauly¹
¹Department of Radiology, Stanford University, CA; ²University of California San Francisco, CA

Introduction Diffusion weighted MRI (DWI) has demonstrated a 36% reduction in ADC following high intensity ultrasound (HIU) induced tissue damage of the prostate. Unlike contrast-enhanced MRI (CE-MRI), the current “gold standard” for assessing tissue viability, DWI can be used repeatedly because it is not affected by contrast material present in the tissue. In addition, real-time DWI can potentially provide insight as to how tissue properties are changing during the procedure, allowing for a physiological measure of treatment completion.

Methods A real-time DWI tool was developed based on EPI with b values <= 1000s/mm², in 3 directions, for a scan time of 6 s for each ADC map. Real-time ADC monitoring during ex vivo tissue ablation was performed with an Insightec Conformal Bone System (37 acoustic Watts for 100 s). Accuracy of the tool was verified by demonstrating the known ADC drop in vivo after transurethral ultrasound ablation of the canine prostate.

Results and Discussion Real time ADC monitoring of ex vivo tissue demonstrated increased ADC values from 0.912x10⁻³mm²/s to 1.153x10⁻³mm²/s at the peak of heating (p=2.6x10⁻⁴, N=4), returning to 0.992x10⁻³mm²/s (p=0.045, N=4) five minutes after ablation. In vivo ADC values changed from 1.93x10⁻³ mm²/s (preablation) to 1.23x10⁻³ mm²/s (80 minutes post-ablation), verifying the known 36% ADC drop seen after in vivo ablation of the prostate.

Hybrid PRF-Thermometry for MRgFUS Brain Applications

V Rieke¹, B Werner², N McDannold³, W Grissom⁴, E Martin², K Butts-Pauly¹
¹Department of Radiology, RSL, Stanford University, CA; ²MR-Center, University Children’s Hospital Zurich, Switzerland; ³Department of Radiology, Brigham and Women’s Hospital, MA; ⁴Imaging Technologies Laboratory, GE Global Research, Munich, Germany

Objective: Clinical applications for MR-guided focused ultrasound in the brain have included tumor ablation and neuropathic pain management, and may include the treatment of Parkinson’s disease, tremor, and epilepsy. MRI has the ability to provide tissue temperature, but the phase subtraction process for PRF thermometry is hampered by motion artifacts. Here we investigate if a hybrid multibaseline/referenceless temperature reconstruction method can reduce these errors compared to the conventional single baseline subtraction method.

Material and Methods: Sagittal brain images from five patients acquired during FUS treatment were reconstructed with the two different methods and temperature uncertainties were compared. We also reconstructed images from normal volunteers without heating. The volunteers were instructed to remain as motionless as possible for the first part of the MR scan, then to purposefully perform tongue or jaw movement, or to take a deep breath.

Results: Temperature maps of one patient undergoing FUS ablation are shown in Fig. 1. The hybrid method shows a clear depiction of the heating spot,

Single baseline subtraction shows severe errors due to brain motion. Hybrid reconstruction shows a clear depiction of the heating spot, almost completely removing the severe errors present when using baseline subtraction.

almost completely removing the severe errors present when using baseline subtraction. Measurements in different areas in the brain (parietal, frontal, cerebellum) showed a 3-fold reduction in temperature uncertainty with the hybrid reconstruction (~0.3°C) compared to baseline subtraction (~1°C) in all areas.

The volunteer images showed temperature fluctuations over time with baseline subtraction possibly caused by pulsation of the brain. These fluctuations were much reduced and hardly noticeable with the hybrid method. Tongue and jaw movement as well as taking a deep breath caused severe errors in baseline subtraction, whereas hybrid reconstruction showed only a minimal increase in temperature errors.

Conclusion: These results show that

the hybrid method is beneficial to monitor FUS ablation in the brain. It is robust to spontaneous events such as swallowing, jaw or tongue movement, or changes in respiration. Hybrid thermometry accurately measures temperature in the brain with less artifacts and errors than baseline subtraction.

Prospective Motion Correction for Diffusion-weighted Breast Imaging

KL Granlund^{1,2}, CJ Moran¹, E Staroswiecki^{1,2}, MT Alley¹, BL Daniel¹, BA Hargreaves¹
Departments of ¹Radiology, RSL, ²Electrical Engineering, Stanford University, CA

The Double Echo Steady State (DESS) sequence [1,2] has been shown to provide high-resolution T2- and diffusion-weighted images in short scan times and with low distortion [3,4]. Such image contrast is useful for improving the specificity of breast MRI [5,6] without the need for an exogenous contrast agent. This steady-state sequence can also be used to quantify T2 and ADC [7,8]. However, the DESS sequence, like all diffusion-weighted sequences, is sensitive to motion, and breast imaging is affected by cardiac, respiratory, and bulk patient motion. We evaluated different techniques for reducing the motion artifact in DESS imaging of the breast including breath holding, physiological gating, and non-sequential phase encode ordering.

We compared a standard DESS scan to a breath-held scan, a cardiac-gated scan, a respiratory-gated scan, a cardiac- and respiratory-gated scan, and an

Top image shows a patient scanned with the standard DESS sequence. Motion artifact causes signal to appear in the center of the image, where there is no tissue. The motion artifact obscures the anatomy, impeding diagnosis. Bottom image shows a patient scanned with elliptic-centric phase-encode ordered DESS sequence. The motion artifact is visually suppressed, and a cyst is clearly seen on the right side of the image.

elliptic-centric phase-encoded scan. The breath-held scan slightly reduced the motion artifact, but limited the resolution and field of view that we could acquire in the limited scan time (~30s). The physiological gating did not sufficiently reduce the artifact and the resulting scan times were prohibitively long: the cardiac-gated scan and respiratory gated scans were twice as long as the standard scan, and the cardiac- and respiratory-gated scan was four times as long as the standard scan. Using elliptic-centric phase encode ordering (phase encodes near the center of k-space are acquired first [9]) visually suppressed the motion artifact without affecting the scan time.

The DESS sequence results in images with much lower distortion than the standard DWI sequence, though it is still sensitive to motion. We found that using

an elliptic-centric phase encoding order results in the best improvement in image quality and does not increase the scan time or limit resolution. Further improvements in image quality may be possible with retrospective correction.

Magnetic Resonance Research

Musculoskeletal MRI at 7.0T: Relaxation Times and Image Contrast

CD Jordan^{1,2}, M Saranathan¹, E Starosweicki^{1,3}, N Bangerter⁴, BA Hargreaves¹, GE Gold¹
Departments of ¹Radiology, ²Bioengineering, ³Electrical Engineering, Stanford University, CA; ⁴Electrical & Computer Engineering, Brigham Young University, Provo, UT

The purpose of our study was to measure the relaxation times of musculoskeletal tissues at 7.0T, to compare them with 3.0T, and to optimize musculoskeletal MRI methods at 7.0T. In the knees of five healthy volunteers for each measurement, we measured the T1 and T2 relaxation times of cartilage, muscle, synovial fluid, bone marrow and subcutaneous fat at 7.0T. The T1 relaxation times were measured using a Spin-Echo Inversion Recovery Sequence at six inversion times. The T2 relaxation times were measured using a Spin-Echo sequence with seven echo times. Accuracy of the T1 and T2 measurements was verified in phantoms. The measurements of T1 and T2 were compared with the same volunteers at both 3.0T and 7.0T. The relaxation times will be used to develop high resolution protocols for proton density fast spin echo sequences, T2-weighted fast spin echo sequences, and 3D CUBE sequences at 7.0T that had similar fluid-cartilage contrast as the standard clinical protocols at 3.0T. MRI at 7.0T can ultimately be used to improve resolution in musculoskeletal imaging.

Images of knee of healthy volunteer obtained at 3.0T and 7.0T: a) Sagittal Proton Density-FSE at 3.0T with an in-plane resolution of 0.11mm² b) Sagittal Proton Density-FSE at 7.0T with an in-plane resolution of 0.028 mm² c) Sagittal T2-weighted-FSE at 3.0T with an in-plane resolution of 0.159 mm² d) Sagittal T2-weighted-FSE at 7.0T with an in-plane resolution of 0.057 mm²

RF Induced Heating On or Near Passive Metallic Implants

U Monu¹, P Worters², GE Gold², BA Hargreaves²
Departments of ¹Electrical Engineering, ²Radiology, Stanford University, CA

As MRI is a key imaging modality used for orthopedic patient care, the safety of commonly used metallic implants in an MRI environment is important. Metallic implants can cause elevated energy deposition near the implant and induce local tissue heating. This, combined with reported cases of pain, heating and burns [1], means there is a need to thoroughly evaluate and quantify the RF power on the tissue surrounding metallic implants.

This study addresses this issue by measuring temperature changes at points of possible maximum SAR deposition, on three common metallic implants: shoulder (180mm long), hip (205mm long) and spinal pedicles (150mm long). Temperature measurements were obtained with and without the metallic implant at 1.5T and 3T in a 30kg rectangular shaped gel phantom that simulates the electrical and thermal properties of the human body. Measured temperature differences for three consecutive runs over a 15min scan period were obtained.

Measured local temperature difference averaged for three consecutive runs, over a 15min scan period on the shoulder implant (Figure1), hip implant (Figure 2) and spinal implant (Figure 3)

High-Resolution 3D T2-Weighted Imaging for Improved Lesion Characterization in Breast MRI

CJ Moran¹, AN Nnewihe^{1,2}, BL Daniel¹, KL Granlund^{1,3}, BA Hargreaves¹
Departments of ¹Radiology, ²Bioengineering, ³Electrical Engineering, Stanford University, CA

Breast MRI has emerged as a promising adjunct to mammography for the detection and diagnosis of breast cancer. In particular, MRI has shown promise in women that have a high risk of developing breast cancer based on genetic predisposition or family history [1]. The strength of breast MRI is that most malignant lesions are detected, however, distinguishing benign from malignant lesions can be challenging. The inability to clearly determine that a lesion is benign can lead to unnecessary biopsies and follow-up exams.

The Body MRI group at Stanford has been working on multiple techniques to improve the diagnostic capabilities of breast MRI. The purpose of this specific project is to provide high-resolution, high-SNR T2-weighted breast images by combining a new GE 3D T2-weighted sequence (FSE-Cube) [2] with a prototype breast coil [3]. T2-weighted images have been shown to help in the characterization of benign lesions, but inherent limitations of conventional T2-weighted methods restrict this information. The GE FSE-Cube sequence

GE FSE-Cube images (0.7 mm3 voxel size) reformatted in three orthogonal planes (a.d: axial, b.e: coronal, c.f: sagittal) demonstrate the improved depiction of fine structural detail available with the prototype breast coil (d-f) in comparison to the reformatted images (2.25 mm3 voxel size) from a commercially available 8-channel coil (a-c). The improved depiction of fine structural detail in all reformats may impact the diagnostic utility of T2-weighted images in the breast as certain structural lesion characteristics differ between benign and malignant lesions.

that we utilize addresses some of these limitations and thus provides high-resolution T2-weighted images in clinically feasible scan times. The prototype breast coil developed by our group achieves 3-4 times improvement in SNR in comparison to a clinically available breast coil, further facilitating the acquisition of very high-resolution images.

Signal-to-noise and resolution comparisons were performed with the FSE-Cube sequence in volunteers and demonstrated a 4 times improvement in SNR in the T2-weighted GE FSE-Cube images using the prototype coil and a 65% reduction in voxel size. In asymptomatic volunteers, the improved resolution allows for clear depiction of fine tissue structure in the T2-weighted images (Figure) thus potentially expanding the diagnostic utility of these images as clear depiction of fine tissue structure can help in the characterization of benign lesions. Studies of this method in patients with biopsy-proven lesions are ongoing.

Novel Variable Voxel Intensity Correction Scheme and Application to Breast Imaging

A Nnewihe^{1,2}, K Sung¹, BL Daniel¹, BA Hargreaves¹
Departments of ¹Radiology, RSL, ²Bioengineering, Stanford University, CA

High-density surface coil arrays have been used for attaining highly accelerated, high-resolution images for brain, breast and cardiac MRI studies. Due to the layout and size of the coil elements, these arrays usually exhibit sensitivity variations across the field of view. Several intensity-correction schemes have been investigated in literature, and many of these algorithms significantly change the spatial noise profile. Especially, in cases with large coil sensitivity variations, these corrections can obscure the overall image quality. In this study, we introduce a novel variable voxel size intensity correction method that reduces intensity variations across the image while keeping the desired noise profile. This is a new approach for intensity correction as it involves lowering spatial resolution in low sensitivity areas in order to gain SNR. For in vivo breast imaging, we compare this novel technique to two commercially available techniques: PURE (Phased array UniforMity Enhancement) and SCIC (Surface Coil Intensity Correction) [GE Healthcare]. PURE corrects field inhomogeneities using a low-resolution proton density weighted calibration scan. SCIC utilizes statistics from the actual image for inhomogeneity correction and does

T1W Axial Images of Healthy Volunteer. We windowed images a) - d) at the same level relative to the brightest voxel in each image. SCIC shows subpar visualization of the chest wall in some areas (see arrow), and there is noticeable noise amplification between the breasts using PURE (see zoomed-in portion). The variable voxel approach provides clear visualization of the chest wall and breast, while minimizes the noise at the expense of reduced spatial resolution in peripheral areas.

not require a calibration scan. Each technique shows improved signal uniformity in the breasts. Using the correction techniques, the glandular structures at the posterior of the breast become more isointense with the anterior of the breast. However, the PURE algorithm shows noise amplification at the background and between the breasts (see zoomed portion), while the variable voxel technique minimizes this added noise at the expense of spatial resolution in these areas. The SCIC image is less noisy when compared to PURE, but SCIC has poorer visualization of some areas of the chest wall (see arrow) in comparison to the other two techniques. Figure 1(bottom) shows the increase in voxel volume with reference to the original image.

Simultaneous Fat Suppression and Band Reduction with Large-Angle Multiple-Acquisition bSSFP

B Quist¹, BA Hargreaves¹, T Cukur², GR Morrell³, GE Gold¹, NK Bangerter^{3,4}
Departments of ¹Radiology, ²Electrical Engineering, Stanford University, CA; ³Department of Radiology, University of Utah, Salt Lake City, UT; ⁴De-
partment of Electrical & Computer Engineering, Brigham Young University, Provo, UT

Balanced steady-state free precession (bSSFP) MRI is a rapid and SNR-efficient imaging method, but suffers from character-
istic bands of signal loss in regions of large
field inhomogeneity. Several methods have
been developed to reduce the severity of these
banding artifacts, typically involving the ac-
quisition of multiple bSSFP data sets. Fat
suppression with bSSFP is also challenging;
most existing methods require an additional
increase in scan time, and some are incompat-
ible with bSSFP band-reduction techniques.

This work was motivated by the need for
both robust fat suppression and band reduc-
tion in the presence of field inhomogeneity
when using bSSFP for flow-independent pe-
ripheral angiography. The large flip angles
used in this application to improve vessel
conspicuity and contrast lead to SAR con-
siderations, longer TR, and increased sever-
ity of banding artifacts. In this work, a novel
method that simultaneously suppresses fat and reduces bSSFP banding artifact with
the acquisition of only two phase-cycled bSSFP data sets is presented. The tech-

Maximum intensity projection images of the 3D bSSFP dataset of the lower leg of a normal
volunteer at 1.5T with the proposed Large-Angle Multiple-Acquisition (LAMA) bSSFP recon-
struction with fat suppression (left), and standard root sum-of-squares reconstruction without fat
suppression (right). The LAMA bSSFP effectively suppresses fat while eliminating banding.

nique exploits the near-sinusoidal shape
of the bSSFP off-resonance spectrum
for many tissues at large (>50 degrees)
flip angles. The spectral profiles can
be shifted to approximate a sine and
cosine by incrementing the phase of
the RF pulse by some $\Delta\phi = 0^\circ$ and $\Delta\phi$
 $=180^\circ$, respectively, from excitation to
excitation. A dataset with spectral pro-
file shifted by an arbitrary Δf can then
be synthesized from the two acquisi-
tions using the relationship $\sin(f+\Delta f)$
 $= \cos(\Delta f)\sin(f) + \sin(\Delta f)\cos(f)$. This
relationship is exploited on a voxel-by-
voxel basis, where Δf is chosen so that
the fat signal is in the stop band while
keeping water signal in the pass band.

A maximum intensity projection
(MIP) image of the 3D dataset before
and after fat-suppression with our new
technique is shown in Figure 1. Our new
technique performs quite well, effectively eliminating banding artifact and
accurately suppressing much of the fat.

Simultaneous Estimation of T₂ and ADC in Cartilage with a Modified 3D DESS Sequence

E Staroswiecki^{1,2}, KL Granlund^{1,2}, MT Alley¹, GE Gold¹, BA Hargreaves¹
Departments of ¹Radiology, RSL, ²Electrical Engineering, Stanford University, CA

Osteoarthritis is a degen-
erative joint disease that in-
volves functional, structural,
morphological, and biochemi-
cal changes to the cartilage.
Assessing articular cartilage in
the early stages of disease with
MRI requires techniques that
are sensitive to both cartilage
morphology and matrix chang-
es. T2 mapping and diffusion-
weighted imaging complement
morphological imaging for as-
sessing cartilage disease and
injury. The double echo steady
state (DESS) sequence has been
used for morphological imag-
ing and generates two echoes
with markedly different T2 and
diffusion weighting. Modifying
the spoiler gradient area and flip
angle in DESS allows greater control of the diffusion weighting of both echoes.
Data from two acquisitions with different spoiler gradient areas and flip angles are
used to simultaneously estimate the T2 and apparent diffusion coefficient (ADC) of
each voxel. This method is verified in phantoms and validated in vivo in the knee;

Detail of sagittal modified 3D
DESS images, ADC and T2 maps
of the knee in vivo. Sum-of-
squares image from the modified
3D DESS acquisition with lower
diffusion weighting (a) and with
higher diffusion weighting (b).
The different diffusion weight-
ings clearly result in different
contrasts between cartilage (solid
arrow) and fluid (dashed arrow)
in (a) and (b). Both the DESS T2
map (c) overlaid on (b) and the
standard FSE T2 map (d) overlaid
on a source FSE T2-weighted im-
age exhibit the expected variation
within cartilage, including magic
angle effects. The DESS ADC
map (e) overlaid on (b) does not
show any distortion or blurring,
while the standard SE-DWI ADC
map (f) overlaid on a source FSE
T2-weighted image is clearly
distorted.

estimates from different
regions of interest in the
phantoms and cartilage
are compared to those
obtained using standard
spin-echo methods. Both
phantom and in vivo
validation show remark-
able agreement between
our new method and the
standard methods. However,
our method achieves full-knee T2
maps faster and with fewer
limitations than the standard
method, and ADC maps without
distortions that are typical
of standard methods. High
accuracy, both for simultane-
ous 3D T2 and
apparent diffusion coefficient
measurements, is demon-
strated, while also provid-
ing morphologic 3D images
without blurring or distor-
tion in reason-
able scan times of around
12 min.

Mapping of T2 and ADC in Articular Cartilage Using DESS with B1 Correction

B Sveinsson^{1,2}, BA Hargreaves¹
Departments of ¹Radiology, ²Electrical Engineering, Stanford University, CA

Measurements of T2 and diffusion in articular cartilage can provide a
valuable indication of potential damage or degenerative disease such as osteo-
arthritis. The Double-Echo-Steady-State (DESS) method, a variant of steady
state magnetic resonance imaging, has been shown to provide fast and reli-
able estimates of both parameters[1]. This is achieved by running two DESS
acquisitions with different flip angles and spoiler gradients and comparing the
resulting four acquired echoes to mathematical signal models relating the
echo strengths to the parameters of the tissue. This method, however, is sensi-
tive to unwanted deviations in the applied flip angle during the scan.

We have increased the accuracy of using DESS for estimation of T2 and
diffusion by acquiring a B1 map along with the DESS acquisitions and in-
corporating the flip angle deviations into the fitting of the measurements to
the signal models. The method has been tested on standard phantoms with
the results showing greatly increased robustness to flip angle variations. We
plan to further improve this method by increasing the quality and speed of the
B1 map acquired and tuning the sensitivity of the signal model fit, as well as
increasing the speed of the fit. The method will also be extended to in vivo
measurements.

Quantitative Mapping of T2 and ADC in test phantom with and without B1 correction. Both maps show
improved homogeneity with B1 mapping.

netic Resonance in Medicine. In press. NIH: R01-EB002524

Abdominal MRA using Breath-hold, IR-prep, Dixon bSSFP

PW Worters, M Saranathan, SS Vasanawala, BA Hargreaves
Department of Radiology, Stanford University, CA

(A) MIP of a three-slab, coronal NORISKS acquisition using three 18-s breath-holds. Note the decreasing signal in the iliac arteries due to
reduced arterial inflow. (B) Axial and reformatted coronal MIPs of a two-slab, axial acquisition using two 24-s breath-holds, showing the
renal and mesenteric arteries.

Inflow-based MR angiography methods without administration of an in-
travenous contrast agent have been used successfully in recent years to pro-
vide bright-blood angiograms of the abdominal arteries [1]. However, these
methods typically use free-breathing acquisitions (3-6 minutes) that rely on
respiratory-bellows or navigator-gated schemes. In our experience, subjects
often fall asleep in these free-breathing acquisitions, leading to irregular

breathing patterns and resulting in non-diagnostic
images. We have developed a breath-hold MR
acquisition strategy to avoid the afore-mentioned
pitfalls and improve robustness to breath-hold fail-
ure. This new method, which we call Non-contrast
Outer Radial Inner Square k-space Scheme or
NORISKS, has shown promising initial results in
recent clinical experience [2].

Although NORISKS requires slightly more ef-
fort than free-breathing acquisitions to prepare the
subject, it avoids respiratory compensation failure
(which costs minutes of time) and acquires impor-
tant information in a shorter time.

Also, NORISKS can be extended to a multiple
breath-hold acquisition for larger spatial coverage
of the entire abdominal vasculature using both
axial and coronal acquisitions.

All acquisitions were made on a 3.0 T sys-
tem (MR750, GE Healthcare) with an 8-channel
phased array coil. NORISKS is based on a dual-
echo Dixon balanced SSFP sequence with IR pre-
paration to enable inflow sensitivity and suppress
background and venous signal. The figure shows
maximum intensity projection (MIP) reformats
of two NORISKS acquisitions from two subjects, clearly depicting the
aorta, mesenteric and renal arteries.

In conclusion, NORISKS enables breath-hold acquisitions for ab-
dominal MRA and avoids scan time penalties when respiratory-triggered
schemes fail. The method can be used in axial and coronal planes to
allow increased flexibility.

Flexible Multislice Interleave Ordering for Efficient Acquisition

BA Hargreaves, PW Worters
Department of Radiology, Stanford University, CA

INTRODUCTION: Interleaved multislice imaging is efficient and is widely used in MR. However, particularly for T1-weighted imaging, the number of slices that can be interleaved within the desired repetition time (TR) is often limited. This leads to suboptimal contrast if TR is increased to accommodate all slices, or increased scan time if multiple acquisitions are needed. We present and demonstrate a very simple method that guarantees maximally efficient interleaving of an arbitrary number of slices without the need to change the TR.

METHODS AND RESULTS: Figure 1a-c show the typical interleaving schemes (a,b) and the more efficient approach (c). The key difference is that in the proposed approach, the slices that are excited in a particular TR can vary, and while this may require one extra TR (total) to achieve smooth equilibrium, the overall effect is that any TR less than the TR for full-interleaving can be used, without changing scan time significantly. We demonstrated this method

Multislice acquisition schemes with 5 slices, each requiring 4 excitations. (a) TR=5TS to encompass all slices, with a total time of 20TS. (b) The desired TR of 3TS results in 2 acquisitions and possibly loss of efficiency (8 TRs or 24TS). (c) Filling the required excitations for each slice vertically allows near-perfect efficiency (7 TRs or 21TS). In most cases the efficiency gain over (b) is even greater. (d) Images show different contrast with identical scan times but arbitrary TR choices.

in human scans where 48 slices were interleaved in different ways with completely arbitrary TR choices and no change in overall scan time, but substantial changes in image contrast, as shown in Fig. 1d.

DISCUSSION: The key strategy for flexible and efficient interleaving is to allow arbitrary slice numbers to be excited at different positions within the repetition. This method is compatible with all standard imaging methods such as parallel imaging and partial-Fourier imaging, and different interleave orders. Additionally, the method completely supports many schemes where different slices may require a different number of excitations, such as using a

varying field-of-view or matrix size is for different slices. Overall, this flexible interleaving scheme is trivial to implement, and allows complete flexibility of TR selection for applications including T1-weighted multislice MRI.

Ultra high spatio-temporal resolution liver imaging using a new view ordering scheme and a 2-point Dixon acquisition

M Saranathan, B Daniel, S Vasanawala, BA Hargreaves
Department of Radiology, Stanford University, CA

Both Dynamic contrast enhanced MRI (DCEMRI) and MR angiography (MRA) are challenged by the conflicting requirements of spatial and temporal resolution. Various solutions have been proposed involving combinations of partial Fourier imaging, under-sampling, view sharing and parallel imaging. We propose DISCO (Differential Subsampling with Cartesian Ordering), a pseudorandom k-space segmented view-sharing scheme that minimizes sensitivity to eddy currents and motion for dynamic imaging while dispersing artifacts and residual ghosting. DISCO uses a variable density Cartesian under-sampling scheme. Elliptical ky-kz is segmented into N annular regions, each sub-sampled by a factor of i with the central region fully sampled and the outer regions progressively under-sampled. Note that k-space points are confined to a Cartesian grid, enabling an FFT-based image reconstruction. Temporal footprint was minimized by nearest neighbor view sharing of the under-sampled views, to generate fully sampled k-space at each temporal phase. View sharing was restricted to within a breath-hold, minimizing temporal

enables robust visualization of the peak arterial phase in the liver, critical for diagnosis of fast enhancing tumors like hepato-cellular carcinoma and neuro-endocrine metastases. It also eliminates the need to precise contrast bolus timing schemes. The method can also be applied to other areas like breast and prostate DCEMRI.

blurring and motion mis-registration. DISCO was implemented on a 3D SPGR sequence with a bipolar readout for 2-point Dixon fat-water separation. After a 12s breath-hold, a pre-contrast mask phase is generated. Following injection of Gadolinium contrast, 6-7 phases were acquired in a 25-28s breath-hold with a temporal resolution of ~4s and a 320x224x60 matrix with 3-3.4 mm section thickness. We have demonstrated the use of DISCO in fast multi-phasic contrast enhanced liver imaging with a 32-channel torso-phased array coil, with no compromise in spatial resolution or coverage. The high spatio-temporal resolution

Very high spatio-temporal resolution breast imaging using a pseudo-random variable density view ordering scheme and 2-point Dixon fat-water separation

M Saranathan, S Vasanawala, BA Hargreaves, BL Daniel.
Department of Radiology, Stanford University, CA

Breast dynamic contrast enhanced MRI (DCEMRI) is challenged by the conflicting requirements of spatial and temporal resolution, leading to poor specificity of breast DCEMRI despite a high sensitivity. We propose DISCO (Differential Subsampling with Cartesian Ordering) for ultra fast dynamic breast imaging. DISCO uses a pseudo-random variable density k-space segmentation scheme that minimizes sensitivity to eddy currents while dispersing artifacts and residual ghosting. Elliptical ky-kz is segmented into N annular regions, each sub-sampled by a factor of i with the central region fully sampled and the outer regions progressively under-sampled. Note that k-space points are confined to a Cartesian grid, enabling an FFT-based image reconstruction. Nearest neighbor view sharing of the under-sampled view was used to generate fully sampled k-space at each temporal phase. Keyhole imaging was used to further increase the temporal resolution of the dynamic phases immediately following Gado-

linium injection (~2-3 min). DISCO was implemented with a 3D SPGR sequence with a bipolar readout for 2-point Dixon fat-water separation. A fully sampled 90s pre-contrast mask phase was first acquired. Following injection of Gadolinium contrast, 16-20 dynamic wash-in phases were acquired using the DISCO view sharing and keyhole at a temporal resolution of ~10s. Following this, 4 fully sampled wash-out phases were acquired with a temporal resolution of ~90s. An acquisition matrix of 256x256x160 over a 28 cm FOV and 1.2 mm section thickness was maintained throughout. The ability to switch seamlessly between

Improved Time-Resolved, 3D PC Imaging with Variable Poisson Sampling and Partial Respiratory Triggering

MT Alley¹, MJ Murphy², K Keutzer², M Lustig², SS Vasanawala¹
¹Department of Radiology, Stanford University, CA; ²Department of Electrical Engineering and Computer Science, UC Berkeley, CA

Time-resolved 3-dimensional phase-contrast MR imaging (4D-PC MRI) has been shown to be an important tool in a wide variety of research applications, such as wall shear stress measurements [1], aortic pulse wave velocity measurements [2], and the investigation of flow patterns in the heart [3]. The adoption of this technique in routine clinical imaging is primarily hampered by two issues: The long scan time inherent in the acquisition and the resulting respiratory artifacts that come from free breathing during the study. Parallel imaging can be used to significantly reduce scan time [4], but undersampling patterns suitable for GRAPPA-like reconstructions often result in coherent artifacts in the final images. We have demonstrated the use of variable density Poisson-disc/ellipse pseudorandom sampling [5] in conjunction with the compressed sensing L1-SPIRiT [6,7] parallel imaging reconstruction implemented on general purpose graphics processors (GPGPU) [8]. In addition, we have implemented a

partial respiratory triggering approach to further reduce breathing artifacts with a minimal increase in scan time. This combined approach provides improved image quality and better artifact reduction within clinically viable acquisition and reconstruction times. [1]: M. Transmit B1 Field Inhomogeneity and T1 Estimation Errors in Breast DCE MRI at 3T

K Sung, BL Daniel, BA Hargreaves
Department of Radiology, Stanford University, CA

A measurement of T1 is important to monitor contrast agent concentration using signal intensity in quantitative dynamic contrast enhanced (DCE) MRI [1]. Variable flip angle acquisitions, called DESPOT1, are a common choice to measure T1 since they can provide a fast 3D volumetric T1 mapping [2]. DESPOT1, however, heavily depends on the set of flip angles used, and therefore is sensitive to any flip angle variation. Transmit B1 field (B1) inhomogeneity creates flip angle variations of 30 - 50% across the breast at 3T [3].

We validate the T1 estimation correction by including B1 mapping in our breast DCE imaging protocol. We then compare T1 relaxation in fat (as a validation) with and without compensating B1 variation in a total of 25 patients at 3T.

The image shows T1 maps with and without compensating for B1 inhomogeneity in one subject. The fat only image is displayed for anatomical reference. The T1 map has a substantial T1 difference between the left and right breast while the compensated one shows more uniform T1 across the whole breast. In 25 patients, the average B1 variations were 115.4% (on the left breast) and 82.4% (on the right

breast), which conforms to the literature [3]. The average T1 difference between the left and right ROIs was 52% from uncorrected maps, and was reduced to 7% by including B1 variation. More importantly, the estimated T1 values (374.4 ms and 346.5 ms) were close to the literature-reported values (T1 = 366 ms) [4].

We have shown that severe B1 variations over the breast can cause a substantial error in T1 estimation using DESPOT1 and compensated the error by measuring the actual B1 variation. This improvement in T1 calculation can benefit quantitative breast DCE MRI.

Delta Relaxation Enhanced Magnetic Resonance Imaging

E Lee, BK Rutt
Department of Radiology, Stanford University, CA

A goal of MR molecular imaging is to closely mimic the PET imaging paradigm (high sensitivity, low background) without sacrificing the spatial resolution advantages of MRI. Delta relaxation enhanced MRI (dreMR) aims to accomplish this with dispersive contrast agents that exhibit T1 relaxivity that varies as a function of field. As dreMR requires field-cycling hardware to enable imaging at different fields, a feasible implementation of dreMR is the insertion of a small resistive magnet into a whole body MR system. This setup has achieved dreMR imaging of up to +/- 0.15T, albeit with some image specificity and artifact issues. We aim to develop the next generation of dreMR imaging hardware to cover a significantly wider field strength range; this should markedly improve image contrast and eliminate image artifacts.

We have partnered with Stelar (Mede, Italy) for the development of a next generation magnet capable of producing +/- 0.5T, with an inner diameter of 30mm suitable for imaging of mice. Two important characteristics of the prototype magnet have been measured to date: eddy current (EC) due to dreMR field switching, and interface performance with clinical scanners. The magnet generates scanner-dependent, quantifiable EC that arises from coupling between the pulsed field magnet and the main magnet. In a GE 1.5T Signa, initial EC measurements showed 250Hz field offset per 0.1T dreMR field decaying with a time constant of 20ms, while in a Philips 1.5T, initial EC was 500Hz per 0.1T and the time constant was 100ms. The scanner and the dreMR magnet controller were synchronized via a programmable digital board, with negligible jitter. Proof-of-principle phantom images were acquired showing that our system is capable of producing dreMR images at field of up to +/- 0.36T, which is the highest dreMR field reported to date. We are now developing EC-compensating dreMR field hardware and image processing methods to remove image artifacts.

RF Coil Design for 7 Tesla MRI

J Lu¹, BK Rutt^{1,2}
Depts of ¹Electrical Engineering, ²Radiology, Stanford University, CA

We are currently studying coil design for improving B1+ field uniformity and signal and examining specific absorption rate (SAR) for high field (7T) magnetic resonance imaging (MRI). Among our methods for studying such designs is the use of the finite element (FEM) and finite-difference time domain (FDTD) methods. Such simulation methods allow the solution of Maxwell's equations to generate electric and magnetic fields in and around coils and sample. Accurate calculation and visualization of such fields would allow us to optimize the coil parameters to increase B1+ signal and uniformity and reduce SAR (absorbed power: proportional to E field squared). We have also performed studies of the Butler matrix, which is essentially a hardware implementation of a Fourier transform. Using such a stage before a degenerate birdcage provides intrinsic decoupling between coils allowing for use in parallel excitation.

Gd-based “smart” MRI probes for molecular imaging

P Pandit¹, D Ye¹, J Ronald¹, J Rao^{1,2}, BK Rutt¹
Departments of ¹Radiology, ²Chemistry, Stanford University, CA

Our group has devised a novel platform for the development of “smart” probes based on biocompatible chemical reactions where Gd-containing molecules, under the control of pH, disulfide reduction and/or enzymatic cleavage, get activated to form magnetic nanoparticles with enhanced relaxivity (Figure a). Two separate condensation schemes are being tested; one based on intramolecular polymerization (GL scheme)[1], and the other on intermolecular cyclization (DJ scheme) [2]. We have assessed the MR properties of these two smart probe schemes in living cells (breast carcinoma cell line MDA-MB-468) and compared the results with the commercially available cell-labeling agent, GdF-M.

Activatable and non-activatable forms of the probes for both GL (GL62 and GL141) and DJ (DJ137 and GJ171) schemes were prepared as previously described [1,2]. 4 million cells were incubated with GdF-M, GL62, GL141, DJ137, DJ171 (~250 uM) for 2, 4, 8, and 24 hours respectively. Following incubation, the cells were washed, fixed and centrifuged to form pel-

lets. Cell pellets were then imaged at 0.5T, 1.5T and 3T at 35 °C and T1 measurements made from these images. Relaxation rates (R1) were determined as 1/T1. Longitudinal relaxivities, r1 (mM-1s-1) were calculated as the slope of R1 vs [Gd] after the determination of true Gd concentration of each cell pellet by ICP-MS measurement.

For the same incubation concentration, the cellular uptake of the “smart” probes was lower than that for GdF-M (Figure b). Nonetheless, both non-activated forms of the “smart” probes showed similar or higher MR relaxivity than GdF-M, with an additional increase after activation, particularly at lower field strengths (80% for DJ, 30% for GL at 0.5T) as can be seen in Figure c. We hypothesize that the increased rotational correlation time (τR) due to nanoparticle formation results in relaxivity amplification after activation. These results successfully demonstrate the in cellulo behavior of our “smart” MRI probes.

Fast B1+ Mapping using an Optimized, Asymmetric Bloch-Siebert Method

M Saranathan¹, M Khalighi², BK Rutt¹
¹Department of Radiology, Stanford University, CA; ²Global Applied Science Lab, GE Healthcare, Menlo Park, CA

B1+ mapping is important in a number of high-field imaging applications including multi-transmit rf pulse design and accurate MR relaxometry. The recently proposed Bloch-Siebert (BS) B1+ mapping method [1] circumvents spoiling and saturation issues faced by magnitude-based methods such as Actual Flip-angle Imaging (AFI) [2] and the Double Angle Method [3] and its variants. While the BS method is relatively fast due to its T1 insensitivity, its accuracy depends on the power of the BS pulse, which is SAR limiting, especially at 7T. This SAR limit can prolong acquisition times, especially for multiple transmit channel B1+ mapping applications. We have developed a novel, fast whole brain 3D Bloch-Siebert B1+ mapping method that is optimized for very short scan times and/or low SAR and demonstrate isotropic whole human

References/Funding Source GE Healthcare Tiger Team

brain B1+ mapping in scan times on the order of 30 seconds at 3T and less than a minute at 7T. The main features include: a. elliptical k-space ordering with elimination of the corners of k-space (70% reduction in scan time); b. use of optimized Bloch-Siebert pulse with 4 ms width and 2000 Hz offset compared to the 6 ms 4000 Hz offset conventional (Fermi) pulse resulting in SAR reduction by ½ or ANR increase by 2; c. acquisition of the second scan on-resonance with no BS pulse or using the Bo map data for phase correction, reducing the scan time and SAR.

mcDESPOT in Longitudinal Multiple Sclerosis Studies

J Su¹, H Kitzler², M Zeineh¹, C Harper-Little³, A Leung⁴, M Kremenchutzky⁵, S Deoni⁶, BK Rutt¹
Departments of ¹Radiology and Electrical Engineering, Stanford University, CA; ²Neuroradiology, Technische Universitaet Dresden, Dresden, Germany; ³Robarts Research Institute, ⁴Diagnostic Radiology and Nuclear Medicine, ⁵Clinical Neurological Sciences, University of Western Ontario, London, Ontario, Canada; ⁶Engineering, Brown University, Providence, RI

Using the whole-brain, myelin-selective MR method, multi-component Driven Equilibrium Single Pulse Observation of T1 and T2 (mcDESPOT), we examined the development of disease in a cohort of patients and controls at baseline and 1 year; the first longitudinal application of this new MR methodology. The baseline cross-sectional study revealed that measures derived from a voxel-wise comparison of myelin water fraction (MWF) in standard space between a subject and the normal control population was highly sensitive to abnormalities in early MS cases. Continuing with the longitudinal follow-up, this measure has also demonstrated statistically significant changes in definite MS patients compared to controls, while the coarse EDSS clinical disability score was unable to detect any change. These measures are promising new markers for assessing the progression of disease. Further study is being conducted with the pre-MS and relapsing-remitting subtypes. These patients have the best chance of having successful disease course-altering treatment and are being tracked carefully with scans every month for half a year or longer. These studies represent a major litmus test for mcDESPOT and its future application to MS.

CT-PRESS Spiral MRSI with Multiple Dualband Frequency-Selective RF Pulses

M Gu¹, DM Spielman¹, NM Zahr², A Pfefferbaum², EV Sullivan^{2,3}, D Mayer^{1,2}
Departments of ¹Radiology, ³Psychiatry & Behavioral Sciences, Stanford University, CA; ²Neuroscience Program, SRI International, Menlo Park, CA

Using effective homonuclear decoupling, constant-time point-resolved spectroscopy, CT-PRESS, has been proposed for the detection of coupled resonances such as glutamate (Glu) and myo-inositol (mI). As a 2D spectroscopy technique, it requires long minimum scan times for multivoxel applications, prohibiting wide spread use in clinical settings. To shorten the minimum scan time, CT-PRESS has been combined with fast spiral spatial encoding. To avoid lipid contamination, however, the method usually employs either the excitation of a restricted brain region using PRESS volume pre-selection, losing metabolite signals from subcortical regions, or applies inversion recover, resulting in reduced SNR. Recently, a robust suppression scheme using multiple dualband frequency-selective RF pulses has been proposed to suppress both water and lipids and thus provide whole-brain coverage without metabolite signal loss. Here, we combine this suppression technique with the CT-PRESS based spiral spectroscopic imaging sequence for improved detection of metabolites of Cho, Cre, mI, Glu, Gln and NAA with whole-brain coverage. The effectiveness of the multiple dualband RF pulses was demonstrated in an in vivo human study within an acquisition time suitable for clinical study. Results demonstrate effective water and lipid suppression and undisturbed metabolite spectra.

Metabolic Kinetics of a Glioma Model using Hyperpolarized 13C MRSI

JM Park^{1,2}, S Josan^{2,3}, T Jang⁴, M Merchant⁴, Y-F Yen⁵, R Hurd⁵, L Recht⁴, D Spielman^{1,2}, D Mayer^{2,3}
Departments of ¹Electrical Engineering, ²Radiology, ⁴Neurology and Neurological Sciences, Stanford University, CA; ³SRI International, Neuroscience Program, Menlo Park, CA; ⁵Applied Science Laboratory GE Healthcare, Menlo Park, CA

¹³C Magnetic Resonance Spectroscopy (MRS) has been used to study in vivo tumor metabolism in brain tumor models, and the altered energy metabolism was confirmed by the elevated production of ¹³C-labeled lactate (Lac) in tumor tissue. DNP (Dynamic Nuclear Polarization) and the recent development of a dissolution process that retains polarization into the liquid state enables the real-time investigation of in vivo metabolism with more than 10,000-fold signal increase over conventional ¹³C methods. Recently, a study showed the feasibility of using hyperpolarized [1-¹³C]-pyruvate (Pyr) for evaluating in vivo metabolism of a human glioblastoma xenograft in a rat brain at a single time point. In this work, we measured the kinetics of pyruvate metabolism in a glioma brain tumor model using the hyperpolarized ¹³C technique with the fast spiral CSI (Chemical Shift Imaging) sequence, and compared the metabolism kinetics from three different ROIs (Region of Interests): brain tumor, normal brain, and vasculature. In vivo results clearly demonstrated the kinetics of the brain tumor metabolism with comparison to those of normal brain

Time-averaged metabolic images of (A) Pyr and (B) Lac computed from three 2D dynamics studies on the same rat (RatC6_2). (C) Voxels selected for ROI analysis: Tumor (Green), Normal brain (Blue), Vasculature (Red). (D) The histology image of the scanned slice.

and vasculature. The Pyr signal also provided an estimate of tissue perfusion in which blood-brain barrier breakdown results in the Pyr curve from the tumor ROI approaching that from the vascular ROI in some animals. Robust dynamic curves of Pyr and Lac were achievable repeatedly with 3 seconds of temporal resolution using the variable RF excitation angle on a single slice, whereas bicarbonate signal detection was limited by the SNR. We also scanned with a recently developed dynamic volumetric spiral CSI sequence covering the entire brain (n=1), with and without additional ¹²C-Lac in the dissolution buffer. Lac peak, SNR, and CNR were improved by 15.8 %, 4.68 %, and 6.92 % compared to those obtained with a normal NaOH buffer, identifying isotopic exchange as an important process in ¹³C-Lac labeling.

Adiabatic B1 Shimming Algorithm for Multiple Channel Transmit at 7T

P Balchandani¹, MM Khalighi², SS Hsieh^{1,3}, K Setsompop⁴, J Pauly³, D Spielman¹
Departments of ¹Radiology, ³Electrical Engineering, Stanford University, CA; ²Global Applied Science Laboratory, GE Healthcare, Menlo Park, CA; ⁴A.A. Martinos Center for Biomedical Imaging, Harvard Medical School, Massachusetts General Hospital, Charlestown, MA

Adiabatic B1 shimming is a hybrid high-field imaging approach that combines the flexibility offered by multiple transmit RF channels with the B1-immunity of custom adiabatic RF pulses. In this work, a simulated annealing (SA) optimization algorithm was developed to determine the RF amplitude and phase adjustments to adiabatic RF pulses played on individual transmit channels. The amplitude and phase of the pulses are chosen to maximize the percentage of the final B1 field over the region of interest (ROI) that exceeds the adiabatic threshold for the applied RF pulses. The adiabatic B1 shimming algorithm was applied to 2-channel and 8-channel 7T B1 transmit maps and the resultant shim values were

Figure 1: (A) B1 maps for a spherical water phantom obtained from a 2-channel (C1, C2) 7T transmit setup. (B) RF amplitude achieved when adiabatic B1 shimming algorithm is applied. (C) Simulated magnitude of slice profile for 180° adiabatic SLR pulse when using B1 shim values from (B). Results from the same experiment and simulations performed in vivo are shown in (D-F). High uniformity in the flip angle is achieved over the entire slice by ensuring RF amplitudes remain above the adiabatic threshold.

tested in simulation. Greater than 95% uniformity was achieved for the simulated flip angle in phantoms and in vivo, when applying the B1 shim values obtained using our optimization algorithm. Input amplitudes are within hardware limits and worst case SAR is lowest when using a simulated annealing approach to minimization. We plan to insert the adiabatic 180° pulse used in simulations into a standard GRE sequence as an inversion pulse and test the efficacy of inversion over the ROI when compared to conventional and adiabatic 180° inversion without B1 shimming. Values registered on the SAR monitor will also be compared. Future work will be focused on optimizing the loss function for the minimization algorithm to more accurately reflect global SAR.

References/Funding Source Balchandani, et al, Adiabatic B1 Shimming Algorithm for Multiple Channel Transmit at 7T, Annual Scientific Meeting of the ISMRM, Montreal, CA, May 2011, p. 3517. Lucas Foundation, NIH R01 MH080913 and GE Healthcare.

RF excitation scheme effects in dynamic volumetric imaging of hyperpolarized [1-13C]-pyruvate

S Josan^{1,2}, R Hurd³, AB Kerr⁴, Y-F Yen³, PE Larson⁵, A Pfefferbaum^{1,6}, D Spielman², D Mayer^{1,2}
¹SRI International, Menlo Park, CA; Departments of ²Radiology, ⁴Electrical Engineering, ⁶Psychiatry and Behavioral Sciences, Stanford University, CA; ³GE Healthcare Applied Science Laboratory, Menlo Park, CA; ⁵Dept of Radiology and Biomedical Imaging, UC San Francisco, CA

Recent studies have demonstrated dynamic metabolic imaging of hyperpolarized pyruvate (Pyr) and its metabolic products for a wide variety of applications. While 3D techniques permit the largest volumetric coverage, they require a large number of RF excitations, which can have a substantial impact on the shape of the dynamic response, the calculation of apparent rate constants, and signal to noise ratio (SNR) averaged over the response. Multiband spectral-spatial RF pulses provide an efficient use of hyperpolarized magnetization for dynamic imaging by using a low excitation flip angle for the injected substrate to preserve its magnetization for subsequent conversion and a higher flip angle for the metabolic products to increase their SNR. However, due to different tissue perfusion, i.e., in- and outflow rates, and metabolic activities, the optimal excitation scheme might depend on the specific organ. This work investigates the performance of

different flip angle schemes in multiple organs. Dynamic 3D ¹³C data were acquired for kidney and liver using the 1°/4°, 2°/8°, 5°/20° multiband or 5°/5° flip angle schemes, and for brain using the 2°/8° and 5°/20° schemes. Comparing the Lac SNR from the weighted average images, the average ratio of SNR of 2°/8° to SNR of 5°/20° was: brain=1.44±0.08; kidney=1.27±0.24; liver=1.11±0.07. The relative SNR ratios of 1°/4°:2°/8°:5°/20° were 0.74:1:0.84 in kidney and 0.74:1:0.9 in liver (in 1 animal). The SNR of 2°/8° relative to 5°/5° was 1.13 in kidney and 1.26 in liver (in 1 animal). Overall, the 2°/8° excitation scheme for dynamic 3D imaging provides good SNR for a wide range of transport kinetics and metabolic activity allowing estimation of tissue specific apparent rate constants.

Quantitative Positive Contrast MRI of Magnetotactic Bacteria

S Josan^{1,2}, A Hamilton³, M Benoit³, C Cunningham⁴, D Spielman², A Matin³, D Mayer^{1,2}
¹SRI International, Menlo Park, CA; Departments of ²Radiology, ³Microbiology and Immunology, Stanford University, CA; ⁴Sunnybrook Health Sciences Center, Toronto, ON, Canada

Contrast agents incorporating superparamagnetic iron-oxide (SPIO) nanoparticles have shown great promise in visualizing labeled cells using MRI. The objective of this work is to explore techniques for improvements in MRI of cancer using genetically encoded magnetite as a contrast agent. The magnetotactic bacteria *Magnetospirillum magneticum* AMB-1 endogenously produce magnetite particles, and have been shown to generate positive MRI contrast in mouse xenograft tumors using T1-weighted MRI [1]. However, as the T2 shortening effect of the magnetite on the signal intensity surpasses the T1 effect, the enhanced contrast peaks within a certain range of magnetite concentration, preventing quantitative assessment. Several techniques exist for visualization of the magnetite particles, but accurate quantitation remains challenging. In this work, two positive contrast imaging techniques were implemented on a 7T small-animal scanner and evaluated for quantitative detection of

the magnetite particles. Figure 1 shows a GRE image as well as positive contrast images of the phantom. Both the off-resonance excitation and the SGM post-processing techniques visualize the magnetite spots well, with good background suppression. Figure 1d shows that a linear correlation exists between the iron concentration and the sum of the signal intensity of all “positive contrast voxels” within a region-of-interest at the spot location. A voxel was considered “positive contrast” if its signal intensity was >3 times the standard deviation above the background signal level. The two methods showed different slopes for the signal dependence on concentration highlighting their different sensitivities. Future work will involve further investigating the sensitivity of the two methods and the minimum detection limit of Fe concentration for both techniques and applying these in an in vivo tumor model.

Fast Volumetric Imaging of Ethanol Metabolism in Rat with Hyperpolarized [1-13C]-Pyruvate

S Josan^{1,2}, D Spielman², Y-F Yen³, R Hurd³, A Pfefferbaum^{1,4}, D Mayer^{1,2}
¹SRI International, Menlo Park, CA; Departments of ²Radiology, ⁴Psychiatry and Behavioral Sciences, Stanford University, CA; ³GE Healthcare Applied Science Laboratory, Menlo Park, CA

Rapid, time-resolved, volumetric imaging of hyperpolarized pyruvate (Pyr) and its metabolic products lactate (Lac) and alanine (Ala) allows the measurement of metabolic activity in different tissues and can be useful to distinguish between normal and diseased tissues. This work applies dynamic 3D magnetic resonance spectroscopic imaging (MRSI) to investigate Pyr metabolism modulated by ethanol. Ethanol is metabolized in the liver via the breakdown of ethanol to acetaldehyde and acetaldehyde to acetate. Both of these reactions reduce the coenzyme nicotinamide adenine dinucleotide (NAD+) to NADH. Thus, ethanol consumption leads to accumulation of NADH in the liver. Because NADH is also a coenzyme in Pyr-to-Lac conversion, this altered liver metabolic state created by ethanol can be interrogated by hyperpolarized Pyr measurements. Spielman et al have previously reported MRS measurements of hyperpolarized Pyr to study rat liver metabolism modulated

13C MRSI can provide improved rate-constant estimates by allowing the analysis of spectra from organ-specific regions-of-interest (ROIs). This work extends the 2D spiral MRSI sequence to provide volumetric coverage and applies it to ethanol metabolism. We demonstrate time-resolved volumetric metabolic imaging of hyperpolarized ¹³C Pyr and its metabolic products using an undersampled spiral CSI sequence, with an acquisition time of 4.5 s for a nominal 5mm isotropic resolution. The dynamic 3D acquisition allows the analysis of spectra from organ-specific ROIs, thus providing improved rate-constant estimates.

Among its many applications, hyperpolarized [1-13C]-pyruvate is used to study cardiac metabolism in healthy and diseased states. The fact that lactate has low toxicity and serves as an important energy source for the heart suggests that hyperpolarized lactate might be an alternative substrate for probing heart metabolism. Chen et al. demonstrated the feasibility of both polarizing [1-13C]-lactate and detecting its metabolic conversion in vivo. The aim of this work was to apply hyperpolarized [1-13C]-lactate to the measurement of cardiac metabolism and compare it to [1-13C]-pyruvate as a substrate. Comparing the time courses of Pyr, Lac, and Bic acquired with FID after injections of hyperpolarized [1-13C]-pyruvate and [1-13C]-lactate, both isotopic exchange and metabolic flux contribute to the conversion between Pyr and Lac as the lactate dehydrogenase (LDH) catalyzed reaction is readily reversible. By contrast, the appearance of Bic reflects

product of hyperpolarized [1-13C]-lactate can be detected in the heart. Therefore, hyperpolarized lactate can be used as an alternative substrate to probe cardiac metabolism.

Reduced Field of View Imaging for Twice-Refocused Diffusion EPI using a Perpendicular Refocusing Slab

RL O'Halloran, M Aksoy, ES Choi, R Bammer
Department of Radiology, Stanford University, CA

Introduction: The single-refocused spin echo, requires a large percentage of the TR reducing scan time efficiency. The Diffusion-Weighted Steady State Free Precession sequence (DW-SSFP), however, can have high diffusion sensitivity with short diffusion gradients [1,2]. Here, spiral projection imaging (SPI) readout is used to achieve whole brain coverage and to allow phase navigation by batching interleaves acquired in similar cardiac phases [3].

Methods: MRI: DW-SSFP SPI was performed on a volunteer using a 1.5T scanner. The k-space trajectory was a spiral-in, rotated in 3D to cover the full 3D k-space sphere. Sequence parameters included: isotropic 1.4 mm3 resolution, 280 mm3 FOV, scan time 2 min per direction for 3 diffusion directions, 5000 spiral interleaves per volume, diffusion gradient width 5.5 ms with 1ms ramps, and diffusion gradient strengths 5, 2.5, 1, and 0.5 G/cm

• **Recon:** Reconstruction was done by binning the data into 10 cardiac phases and performing iterative SENSE algorithm [3, 4]. Gridding was performed for comparison.

Results and Discussion: SENSE-reconstructed images are given in Fig 1. In the higher diffusion-weightings (Fig 1a last column) there are residual phase errors. Figure 1b shows 3 orthogonal slices through the volume using the maximum gradient strength, demonstrating the isotropic 3D full brain coverage. Figure 2 shows the improvement achieved by using cardiac binning and SENSE (arrow, b) compared to gridding (arrow, a).

Conclusion: A 3D isotropic high-resolution DW-SSFP technique is demonstrated that covers the whole brain. Cardiac gated SENSE reconstruction was able correct much of the phase errors and led to better image quality than gridding reconstruction.

Benefits of Optical Prospective Motion Correction for Single-Shot DTI

M Aksoy¹, C Forman², D Kopeinigg¹, M Straka¹, R O'Halloran¹, S Holdsworth¹, S Skare³, R Bammer¹

¹Department of Radiology, Stanford University, CA; ²Computer Science, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany;

³Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden

Introduction: Involuntary patient motion causes pixel misregistration and changes the effective diffusion-encoding, which, in turn, results in erroneous estimation of diffusion tensors or higher-order variants (1-3). The most common method of motion correction for DTI is retrospective coregistration of diffusion-weighted volumes to a reference volume. However, retrospective correction methods cannot repair incomplete diffusion-weighted volumes, spin history effects, or non-equidistant sampling of the diffusion-encoding direction space. In this study, we propose to use an adaptive optical tracking system (4) to correct for motion artifacts in single-shot EPI DTI and aim to demonstrate the advantages of this prospective approach over retrospective volume-to-volume realignment.

Methods: Prospective Optical Motion Correction – A small camera was mounted on an 8-channel head coil and acquired images of a self-encoded marker attached to the subject's forehead [5]. The video frames were processed on an external computer. The patient's pose was determined at a rate of 25Hz and the geometry update was sent back to the sequencer in real-time so that the scan volume followed the subject's head with minimum delay.

Figure 1 - Reconstructed FA maps show that, even with retrospective volume-to-volume realignment, motion-related image artifacts remain because of intra-volume motion and spin history effects. Prospectively corrected FA maps show the most similarity with the reference dataset.

Experiments – A single-shot DTI-EPI sequence was used (TR/TE=10sec/75msec, FOV=24cm, 96x96 matrix, 36 3mm slices @ 1mm gap, b=1000 sec/mm2, # diffusion directions = 25 (+3 b=0)). The volunteer was asked to perform mixed (in-plane) shaking and (through-plane) nodding motion throughout the scan, once every ~15 seconds. This scan was repeated with & without prospective motion correction. The data without adaptive motion correction was also reconstructed after retrospective volume-to-volume realignment with SPM8. For reference, two additional datasets were obtained where the subject was asked to stay still and prospective motion correction was turned off and on.

Results and Discussion: Figure 1 shows FA and mean diffusivity maps for DTI experiments using single-shot EPI with 96x96 resolution. The non-corrected FA maps show detrimental motion artifacts. Retrospective correction using volume-to-volume realignment improved the image quality, but artifacts still remain mainly due to intra-volume motion and spin history effects. The dataset with prospective motion correction shows the highest

degree of similarity with the data with no motion.

Introduction: Optimal blood pressure control following acute intracerebral hemorrhage (ICH) remains poorly defined. Blood pressure control may prevent hematoma expansion, while aggressive blood pressure reduction may cause perfusion deficits and subsequent perihematomal ischemia. We investigated perihematomal perfusion in relation to blood pressure reduction using magnetic resonance imaging (MRI) within 24 hours of ICH onset.

Methods: Consecutive prospectively enrolled ICH patients were included if they had an MRI within 24 hours of ICH symptom onset. FLAIR, GRE and perfusion weighted images were acquired and co-registered. T_{max} maps were generated using RAPid processing of Perfusion and Diffusion (RAPID) software. The perihematomal region was defined by outlining the perihematomal edema on FLAIR images and subtracting the inner surface of blood products on the GRE to generate a rim around the hematoma. A T_{max}≥6s was defined as abnormal. Image processing was done using Medical Image Processing Analysis and Visualization software.

1. Relationship between systolic BP changes and T_{max}
2. Systolic BP drops more than 30% are associated with significantly delayed bolus arrival

associated with regional T_{max} values concerning for ischemia. Perihematomal perfusion by MRI may have a role in determining safe thresholds for BP lowering in individual patients. The interaction between regional cerebral perfusion, perihematomal ischemia and neurological status requires further study.

Rapid Diffusion Spectrum Imaging with Partial Q-Spce Encoding

AT Van, RL O'Halloran, S Holdsworth, R Bammer
Department of Radiology, Stanford University, CA

Introduction: Diffusion spectrum imaging (DSI) [1] is a variant of q-space imaging which allows one to measure and interpret the complex diffusion process in microstructures without the necessity of limiting signal models. Despite its great potential, applications of DSI to in vivo studies have been hindered by DSI's long total acquisition time to sample q-space. Many studies have tried to speed up DSI, either by using compressed sensing [2], by multiplexing slices in acquisitions [3, 4], or by using signal models and/or signal decomposition [5-7] at the cost of a loss of generality and sometimes a loss of information. The current approach proposes to reduce the total acquisition time of DSI by employing a partial q-space encoding scheme, similar to the partial Fourier encoding in traditional k-space imaging. The method does not require any signal modeling and is compatible with previously proposed acquisition-based speed-up techniques [2-4].

Methods: The measured DSI signal and the probability distribution function (pdf) of the diffusion process in imaged tissues are related through the Fourier relationship. Since all pdfs are real, from the property of the Fourier transform, the measured q-space data are Hermitian symmetric, meaning S(q) = S*(−q) where S(.) is the measure q-space signal and * represents the complex conjugate operation. This Hermitian symmetry property of the q-space signal allows the acquisition of only half of the q-space signal; the other half can be filled in using the above equation, resulting in 50%

Figure 1: In vivo: ODFs (middle panels), and 2D contours of the 3D propagators (right panels) obtained at a region of interest within the corpus callosum using fully-sampled, and partially-sampled q-space data.

on the FA map. No difference was observed between the ODFs generated by partially-sampled q-space data and the ODFs generated by fully-sampled q-space data. The right panels of Fig. 2 compares the 3D propagators reconstructed from fully-sampled and partially-sampled q-space data. The structure of the propagator is well-preserved in the partially-sampled case. By using partial q-space encoding, the total acquisition time was reduced by 44.4%.

Conclusion: We have shown that partial q-space encoding is an efficient acquisition method for diffusion spectrum imaging. The method is proposed based on the intrinsic property of the diffusion propagator and does not require any signal modeling.

A Geometric Distortion Correction Algorithm to Augment Prospectively Corrected EPI Data

MB Ooi¹, TR Brown², R Bammer¹

¹Department of Radiology, RSL, Stanford University, CA; ²Department of Radiology, Medical University of South Carolina, SC

While prospective rigid-body motion correction can be performed very accurately¹, a secondary effect of head motion is non-rigid image distortion in echo-planar imaging (EPI) caused by changes in the effective shim within the brain². We implemented an approach that uses prospective motion correction in combination with retrospective distortion correction to obtain single-shot EPI scans that are compensated for both rigid motions and susceptibility-induced non-rigid deformations.

Complex EPI-data from the prospectively corrected images³ was saved to generate field-maps for additional retrospective distortion correction. Phase images Φ_n of the nth diffusion scan were unwrapped, and the field variation map ΔB_n calculated: $\Delta B_n = (\Phi_n - \Phi_1)/(2\pi TE)$. ΔB_n thus yields a frequency-difference map (Hz) of the relative field inhomogeneity deviation between the nth and first (reference) time-frame due to the different head positions relative to B_0 . Since field inhomogeneities cause negligible pixel mislocation in the readout direction for EPI, the distortion correction then simplifies into a series of 1D pixel-shifts in the phase-encode direction which – due to the prospective scan-plane tracking – remains “locked” to the patient orientation. To calculate the necessary pixel-shifts, the local ΔB_n is converted into a pixel-shift map $r_n = \Delta B_n/BW_{PE}$, where BW_{PE} is the bandwidth per pixel in the phase-encode direction. A shifting algorithm⁴ was implemented where each

Top row shows a reference image (left), and the difference between an image in the time-series acquired after 5° of head rotation without any correction (right). Bottom row shows that prospective motion correction mitigates the misregistration (left) but geometric distortions still remain (highlighted by arrows). Combined prospective and retrospective correction leaves only minor differences (right).

pixel at location r_n was used to shift the corresponding image pixel. In this manner every nth time-frame was undistorted back to the reference. This (non-rigid-body) distortion correction was retrospectively applied to the (rigid-body) prospectively corrected dataset and yielded considerable improvement over prospective motion correction alone (see figure). Achieving better congruence between individual images is key for applications where multiple volumes are acquired, such as diffusion, perfusion, and functional MRI. The proposed distortion correction algorithm can effectively augment any prospective correction method, as long as the complex EPI data is saved.

Spin- and Gradient-Echo EPI for Imaging of Brain Perfusion with MRI

H Schmiedeskamp¹, M Straka¹, G Zaharchuk¹, NJ Fischbein¹, MG Lansberg², J-M Olivot², GW Albers², ME Moseley¹, R Bammer¹

Departments of ¹Radiology, ²Neurology, Stanford University, CA

A spin and gradient echo (SAGE) EPI sequence that is capable of simultaneously measuring spin- (SE) and gradient-echo (GE) perfusion-weighted imaging (PWI) data was previously introduced). This sequence was adopted from recent work on PWI by merging multi-GE EPI with a combined GE and SE EPI acquisition. Boxerman et al. found a difference in sensitivity to the underlying microvasculature in brain tissue, depending on whether GE or SE images were acquired. The great advantage of SAGE-EPI is that it acquires GE and SE perfusion maps simultaneously, and allows one to relate changes in R2 to changes in R2* for vessel size imaging (VSI). Here, we refined the SAGE-EPI pulse sequence to facilitate the simultaneous acquisition of 5 EPI readout trains, all with echo times TE < 100 ms. Furthermore, the PWI processing pipeline was adjusted such that cerebral blood volume (CBV)

Fig. 1 – PWI maps including CBV, CBF, MTT, Tmax, and VSI in a 76-year old patient with subacute infarct in left posterior MCA territory with enhanced CBV visible on R2 and R2*-weighted CBV maps, suppressed on single echo GE and SE CBV maps (red arrows). Associated increase in MTT, particularly well defined in R2-weighted maps. Single echo MTT maps even show a decreased MTT in questioned area (green arrows).

and cerebral blood flow (CBF) were calculated from R2 and R2* estimates, rather than relative changes in signal intensity, with the goal to produce T1-independent, more quantitative PWI maps. Fig. 1 shows results in case of subacute left posterior MCA infarct. While single-echo based GE and SE PWI maps reflect little to no increase in CBV, PWI maps produced with the help of R2 and R2* resulted in considerably increased CBV in the left temporal lobe (red arrows). Increased mean transit time (MTT) was associated with higher CBV, a common finding in subacute stroke lesions. VSI resulted in a small, but notable drop in vessel size within the area in question, more pronounced on the maps created with the multi-echo $\Delta R2^*/\Delta R2$ approach. In summary, the calculation of PWI parameters could be enhanced by correcting for T1-shortening effects based on the estimates of the transversal relaxation times R2 and R2*.

Behavioral correlates of temporal variations in brain network connectivity

C Chang^{1,2}, X Shen¹, GH Glover^{1,2}

Departments of ¹Electrical Engineering, ²Radiology, Stanford University, CA

Functional connectivity among brain networks, as averaged across a several-minute fMRI scan, has been found to reflect conditions such as neurological disorders and behavioral state. It was recently demonstrated that the coherence between brain networks can display marked variations in magnitude and phase across a resting-state scan, suggesting that connectivity variability, as well as mean strength, may be a relevant index of cognitive state. Here, we used sustained task manipulations (continuous 1-back and 2-back working memory tasks) to probe the causes and potential significance of temporal variability in low-frequency BOLD signal connectivity. After filtering out task-related frequencies (>0.12 Hz), we examined whether variability in connectivity between the default-mode network (DMN) and other brain regions can be modulated by cognitive load, and quantified the degree to which variability can explain individual differences in behavior (reaction time).

Temporal variability in connectivity with the DMN was modulated by task load (Fig. 1); overall, greater variability was observed in the 1-back task, compared to the 2-back task. Across subjects, functional connectivity between the DMN and both the anterior cingulate cortex and caudate was predictive of mean reaction times in both 1- and 2-back tasks. Within subjects, a sliding-window analysis (window size = 1 min) revealed that changes in mean reaction time across the scan were correlated with changes in functional connectivity between the DMN and a cluster in the dorsolateral prefrontal cortex (DLPFC) for both 1- and 2-back tasks, and with clusters in the DLPFC and hippocampus for the 2-back task. These findings contribute evidence that dynamics of network connectivity may relate to inter- and intra-individual differences in behavioral performance, and hence may serve as a meaningful index of cognitive or attentional state.

Influence of Dense Array EEG Cap on fMRI Signal

Q Luo, GH Glover

Departments of Radiology, RSL, Stanford University, CA

Dense-array (>64 channel) EEG systems are increasingly being used in simultaneous EEG-fMRI studies. However, with increasing channel count, dense-array EEG caps can induce more severe signal dropout in the MRI images than conventional systems due to the radio frequency (RF) shielding effect of the denser conducting wire bundle. This study investigates the influence of a 256 channel EEG cap on MRI image quality and detection sensitivity of BOLD fMRI signal. A theoretical model is first established to describe the impact of the EEG cap on anatomic signal, noise, signal-to-noise ratio (SNR) and contrast-to-noise ratio of BOLD signal. Seven subjects were scanned to measure and compare the T2*-weighted image quality and fMRI detection sensitivity with and without the EEG cap using an auditory/visual/sensorimotor task. As shown in the figure, the experimental results indicated that the dense-array EEG cap can substantially reduce the anatomic signal in the brain areas (visual cortex) near the conduct-

Influence of the EEG cap on T2*-weighted image quality and BOLD fMRI signal. The maps of image quality parameters (anatomic signal, noise and SNR) and BOLD activation without and with the EEG cap are obtained from a single subject and overlaid on the corresponding high-resolution structural images to facilitate visual inspection. The signal, noise, and SNR values are normalized to the corresponding average values in the prefrontal brain region, where the shielding effect on the signal and noise is negligible.

Rapid Motions in Pediatric and Clinical Populations

PK Mazaika¹, GH Glover², AL Reiss¹
Departments of ¹Psychiatry and Behavioral Sciences, ²Radiology, RSL, Stanford University, CA

The analysis of neuroimaging data from children with developmental disorders is key to understanding the neural correlates of impaired cognitive development. However, these subjects may not tolerate tight head padding, and rapid head motions may introduce artifacts in fMRI data that can degrade the accuracy of the results. The goal of this study was to quantify the density of rapid motion artifacts for several pediatric and clinical populations. All subjects were prepared before the real scan by practice in a mock MRI scanner in an effort to desensitize them to the sights and sounds of an actual MRI environment. We counted the fraction of scans with rapid motions of more than 0.5 mm/TR using existing fMRI data (254 scan sessions) from a variety of healthy and high motion subject populations. The populations included healthy adults, adolescents, and young children, and subjects with fragile X syndrome, Williams syndrome, Turner syndrome, and bipolar disorder. The rapid motion characteristics are shown as a quartile plot in the figure. Among the healthy subjects, adolescents have more rapid motions than adults, and young children have the most rapid motions. For all the populations (except healthy adults, and females with Fragile X syndrome), there are rapid motion artifacts in the fMRI data for more than half of the data sets. Artifact suppression algorithms must be able to process data with 10% or more artifacts in order to be successful in these populations. The ArtRepair software toolbox is one method that will automatically suppress the residual motion effects and artifacts that occur in fMRI data from these populations. (<http://cibsr.stanford.edu/tools/ArtRepair>).

Distribution of scan sessions by the fraction of artifacts in the data for healthy and clinical populations.

Pseudocontinuous and Velocity Selective Arterial Spin Labeling vs. Gold Standard Xenon CT

D Qiu, ME Moseley, G Zaharchuk
Department of Radiology, RSL, Stanford University, CA

In standard arterial spin labeling (ASL), differences in arterial transit arrival time can be a major source of error in the quantification of cerebral blood flow (CBF). This problem becomes worse in some pathologies, such as stroke, where blood flow is slow and/or there is collateral flow. Recently, velocity-selective ASL (VSASL) has been proposed and is expected to overcome this limitation. However, clinical data on VSASL is rare. In this study, we compared the performance of a 3D-FSE pseudocontinuous ASL (pcASL) with different post-label delay (PLD) times and VSASL, using xenon CT CBF as gold standard. High-quality pcASL, pcASL-VS, and xeCT CBF maps were obtained. VSASL CBF maps, however, have relatively lower SNR due to the use of a saturation rather than inversion labeling pulse. Visually, PLD dependence of pcASL and pcASL-VS CBF measurement was obvious in slow-flow regions, though these were somewhat mitigated at longer PLD's, such as 3s. Overestimation of CBF for pcASL studies with long PLD was seen in regions with delayed arrival, and may reflect differences in the true and assumed T1 decay of the label. Correlation analysis showed that among different PLD times, the strongest correlation with xeCT CBF measurement was found in CBF maps acquired with PLD=1.5s for

both pcASL and pcASL-VS. VSASL had moderate correlation with xeCT measurement, largely attributable to lower SNR in VSASL CBF measurement. In general, differences between VSASL and xeCT CBF values were among the smallest for all ASL sequences, and importantly the standard deviations of these differences were also small, suggesting that VSASL may provide a quantitatively more accurate measurement of CBF in these patients.

To our knowledge, these are the first reports of VSASL in clinical patients with severe prolongations in arterial arrival times. pcASL CBF maps with long PLD more closely approximated xenon CT CBF maps, but required long scan times (8 min) and had relatively poor SNR. The expected PLD dependence of pcASL and pcASL-VS CBF measurements was observed. VSASL provided more accurate absolute CBF measurement, though correlation with xeCT was lower, largely owing to lower SNR. Further development of VSASL techniques may enable accurate CBF measurements in patients with cerebrovascular disease.

Consequences of Multi-echo Fits in Perfusion MRI for the Determination of MTT in Presence of T1-Effects.

M Straka¹, H Schmiedeskamp¹, G Zaharchuk¹, JB Andre¹, J-M Olivot², NJ Fischbein¹, MG Lansberg², ME Moseley¹, GW Albers², R Bammer¹
¹Department of Radiology, Stanford University, CA; ²Stanford Stroke Center, Stanford University, CA

Although it was already pointed out that T1-shortening can be a considerable confounder in DSC-PWI, it has been heavily underestimated so far by the community. While practitioners are aware of potential CBV underestimation due to T1-shortening, time-based perfusion parameters are widely deemed to be immune against confounding effects that primarily influence the calculation of the time course of contrast concentration. In this study, we demonstrate in simulations and on clinical data that current DSC-PWI approaches can also lead to incorrect estimates of MTT, specifically in areas of contrast agent (CA) leakage due to a compromised blood-brain barrier. This can be seen as a confirmatory study for the predictions. With the current trend of neuroimaging migrating towards higher fields and shorter sampling rates, T1 shortening warrants even more attention as these effects will be increased. Here, we show that T1-effects can have considerable consequences for the estimation of MTT, whereas Tmax is more robust against this confounder.

Estimated values of MTT in presence of T1-effects were 50% higher compared to situations in which T1-effects were removed, however, Tmax values did not show any significant differences (data not shown). A very similar behavior was observed in the scanned data. Presence of T1-shortening in a scan performed at 3T and at high temporal resolution (TR = 1.8sec) resulted in considerable differences between multi-echo T2 and T2* DSC-PWI maps and those derived from conventional single-echo GE or SE methods. Specifically,

both single-echo GE and SE derived MTT maps did not show significant increase in the region of the subacute stroke (accompanied by noticeable T1 extravasation), whereas Tmax maps derived from these methods clearly showed alterations in hemodynamics.

In assessment of stroke, the T1-shortening can severely limit the veracity of MTT maps (derived using bolus tracking methods) when not accounted for. This is due to errors in the estimation of contrast agent concentration; to some degree immediately before and during the first pass of the bolus, but to a much greater extent after the first pass. The results shown here might be exaggerated because the GEs were acquired with a 90° flip angle, which could be adjusted towards lower flip angles to reduce the T1 sensitivity. To eliminate this T1 sensitivity entirely and to leverage higher SNR from more optimal flip angles, a SAGE approach as described in this work should be used, ultimately leading to more accurate estimates of tracer concentration and therefore MTT. On the other hand, Tmax appears not to be affected by T1 effects. This is mostly because it is an AIF-corrected bolus arrival map; Tmax is not sensitive to erroneous signal changes predominantly occurring at the tail end of the bolus, but these signal changes are mainly responsible for MTT estimation errors. In summary, when reporting clinical MTT values in addition to Tmax, caution should be exercised, as regions with prolonged MTT might be severely underestimated.

Quantitative Susceptibility Imaging using L1 regularized reConstruction with Sparsity Promoting Transformation: SILC

D Qiu, G Zaharchuk, S Feng, T Christen, K Sung, ME Moseley
Department of Radiology, RSL, Stanford University, CA

The phase image has been shown to provide superb tissue contrast at high imaging field, and reveals anatomical details that cannot be easily identified in magnitude images. Reconstruction of the susceptibility distribution from phase images provides a quantitative measure of tissue properties, but faces many difficulties, including zero points in the convolution kernel. Methods have been proposed to solve the problem. Here we develop a novel method of reconstructing susceptibility distribution from phase images, which borrows ideas from compressed sensing.

Simulation analysis showed that there were residual streaking artifacts in the KM reconstructed susceptibility image while SILC nearly perfectly reconstructed the susceptibility image. For the KM method, the mean estimated susceptibility value inside the tube was found to depend on the truncation level and largely underestimated the true value (0.02ppm). In contrast, for the SILC method, the mean estimated susceptibility value closely approached the true value for a range of values of p.

The SILC method successfully reconstructed susceptibility distributions from the in-vivo human brain data, and the contrast matches known distribution of susceptibility in the brain. The susceptibility image reconstructed using KM method showed lower resolution, possibly due to modification of the kernel; and the values were lower than that in SILC reconstructed image, consistent with simulation results.

We have proposed a novel method (SILC) for reconstructing susceptibility image from field map using L1 regularization with sparsity-promoting transformation. Simulations showed high fidelity of the reconstructed image using SILC to the gold truth for a range of the data consistency penalty parameter p. This quantitative susceptibility imaging technique has many potential applications, including measurement of blood oxygenation level in the vessels, quantification of iron loading in the brain, definition of arterial input function in dynamic susceptibility contrast imaging.

Prescription opioid analgesics rapidly change the human brain.

J Younger, L Chu, N D'Arcy, K Trott, L Jastrzab, S Mackey
Department of Anesthesia, Stanford University, CA

Long-term opioid abuse has been associated with neuroplastic changes in the human brain; however, it is unknown if opioids used over short periods of time and at analgesic dosages can similarly change brain structure. Ten individuals with low-back pain were administered oral morphine for one month (mean daily dosage = 72 mg). Nine other individuals were administered a placebo substance for the same period of time. High-resolution anatomical images of the brain were acquired from participants before and after the one-month morphine or placebo administration. Individuals receiving morphine reported a significant decrease in low-back pain, as well as a significant increase of anxiety and non-significant increase of depression. Grey matter volumetric changes were assessed using tensor-based morphometry. Regional areas of atrophy and hypertrophy were examined on the whole brain, and regions exhibiting a significant change over time were subsequently tested for correlations with morphine dosage. Dosage-correlated grey matter atrophy was observed in the amygdala, and dosage-correlated hypertrophy was seen in the posterior cingulate, hypothalamus, inferior pons, inferior frontal gyrus, superior

temporal gyrus, and cerebellar tonsil. No regions of atrophy or hypertrophy were observed in the placebo group. In order to differentiate neural mechanisms of desirable morphine outcomes (analgesia) from the mechanisms of adverse outcomes, a series of post-hoc correlation tests were performed on the regions evidencing significant neuroplasticity. Self-reported changes in pain intensity, anxiety, and depression were used in the post-hoc correlations. Individuals reporting the greatest pain reduction also showed the most grey matter volume reduction in the hippocampus, and the most volume increase in the posterior cingulate. Increases in anxiety over time were associated with hypertrophy in the posterior cingulate and posterior insula. Increased reports of depression corresponded to atrophy in the oribtofrontal gyrus, and hypertrophy in the dorsal posterior cingulate and mid-cingulate. Prescription opioid analgesics can cause morphologic changes in the human brain after one month of daily administration. Furthermore, the neuroplastic mechanisms underlying the desirable consequences of opioid use may be distinct from the mechanisms of unwanted consequences.

Spin-echo and Gradient-echo PWI CBF vs. ASL CBF: An Initial Comparison

M Straka¹, H Schmiedeskamp¹, G Zaharchuk¹, JB Andre¹, J-M Olivot², NJ Fischbein¹, MG Lansberg², ME Moseley¹, GW Albers², R Bammer¹
Departments of ¹Radiology, ²Neurology, Stanford University, CA

The SAGE PWI sequence [1, 2] leverages on both gradient-echo (GRE) and spin-echo (SE) data for advanced perfusion-weighted imaging (PWI). It also allows quantification of the baseline R2 and R2*, as well as true ΔR2 and ΔR2* changes during the passage of the gadolinium tracer. This sequence allows one to quantify perfusion parameters from both capillaries (via SE data) and arterioles/venules (via GRE data) at high temporal resolution and without T1 contamination. Although current routine PWI scans use primarily the GRE data, it has been long suggested that cerebral blood flow (CBF) values derived from GRE are overestimated due to excessive sensitivity to larger vessels. Here, we compared CBF values from by GRE- and SE-based SAGE CBF to reference arterial-spin labeling (ASL) CBF data.Ten clinical cases were acquired using a 3T GE Discovery MR750 scanner. The study was IRB approved and written informed consent was obtained from each subject.

Our initial results show that CBF derived from SE based maps was approx. 4.8-times smaller than CBF derived from GRE-based maps, and hence the SE

CBF must be corrected with this factor to match GRE CBF values. The 4.8-fold difference was very similar between gray and white matter, and could be considered in future studies. Results also show that SE- and ΔR2-based CBF maps correlate with ASL CBF better than GRE or ΔR2*-based maps as the large vessel contribution present on GRE-based maps tend to obfuscate tissue microperfusion. Our results also manifest that the slope of SE CBF vs. ASL CBF is less than 1.0, and the intercept is non-zero. Specifically, the relation between ASL CBF and SE CBF was different in both gray and white matter, which is most likely caused by sensitivity of ASL to label delay and variable label efficiency in gray and white matter. Based on the correlation coefficient R and visual impression, we conclude that SEbased/ΔR2-based PWI CBF maps are more similar to ASL than those obtained from single-GRE/ΔR2*-based data. However, differences between single-SE and ΔR2-based CBF values require further analysis.

Evaluating an Intensive Behavioral Intervention for Children and Adolescents with Fragile X Syndrome

SS Hall, JL Hammond, KM Hustyi, AL Reiss
Department of Psychiatry and Behavioral Sciences, Stanford University, CA

This study will attempt to overcome putative specific learning dysfunction in children and adolescents diagnosed with Fragile X syndrome (FXS) using a stimulus equivalence (SE) teaching paradigm. Mathematical performance and brain activation prior to and following SE training will be examined. The efficacy of the intervention will be studied in comparison to a control group of gender, verbal IQ, and age-matched individuals diagnosed with non-specific developmental delay (DD) in order to understand the specificity of mathematical dysfunction exhibited by individuals with FXS. Performance in the

targeted skill areas (fraction, pie chart, and decimal conversion) will be compared prior to and following SE training, using functional magnetic resonance imaging (fMRI) and behavioral metrics. It is hypothesized that following SE training, individuals with FXS will show gains in their discrimination of both trained and untrained mathematical relations, and will show increased activation in posterior parietal (PPC) and dorsolateral prefrontal cortex (DLPFC). In addition, we hypothesize that these regions will show increased functional connectivity compared to pre-test measures.

Stress Coping and Brain Development: A Longitudinal MRI Study

JM Nechvatal¹, D Qiu², CL Buckmaster¹, AF Schatzberg¹, ME Moseley², DM Lyons¹
Departments of ¹Psychiatry, ²Radiology, RSL, Stanford University, CA

Coping with early intermittent stress changes the developing brain. Here we describe how these neuroadaptations arise in a longitudinal study of adolescent squirrel monkeys (*Saimiri sciureus*).

T1-weighted anatomical brain images were acquired once each year over the first 3 years of life from monkeys previously exposed to either an intermittent stress coping condition (IS, n = 11) or a no-stress control condition (NS, n = 9). Total gray and white matter brain volumes were determined and voxel-based morphometry (VBM) was used to localize specific regions of volumetric expansion or contraction.

From 1 to 3 years of age, both IS and NS animals exhibited reductions in total gray matter volumes along with white matter increases. Total gray matter reductions were smaller and white matter increases

greater in IS than NS animals. VBM analysis revealed prefrontal gray matter contraction in both IS and NS animals, with additional contraction in anterior cingulate observed only in NS animals. Prefrontal gray matter expansion was observed only in IS animals late in adolescent development. White matter expansion was observed in prefrontal regions for both groups and was greater in IS than NS animals.

These data suggest that larger prefrontal volumes previously reported [1, 2] for two different samples of adolescent IS compared to NS monkeys arise from smaller reductions and not just increased expansion of gray matter tissue. Changes in the density of synaptic connections, dendrites, neurons or glial cells may play a role in refining stress coping-dependent neural circuitry.

Identification of ischaemic stroke subtype currently relies on clinical evaluation supported by various diagnostic studies. The authors sought to determine whether specific diffusion-weighted MRI (DWI) patterns could reliably guide the subsequent work-up for patients presenting with acute ischaemic stroke symptoms. 273 consecutive patients with acute ischaemic stroke symptoms were enrolled in this prospective, observational, single-centre NIH-sponsored study.

Among patients with a thromboembolic DWI pattern, transoesophageal echocardiography was the principal determinant of diagnostic change in 8.8% versus 0% for the small vessel group and 1.7% for the other group

(p<0.01). Among patients with the combination of a thromboembolic pattern on MRI and a negative cervical MRA, transoesophageal echocardiography led to a change in diagnosis in 12.1%. There was no significant difference between groups using a CT-based scheme. Conclusions DWI patterns appear to predict stroke aetiologies better than conventional methods.

The study data suggest an MRI-based diagnostic algorithm that can potentially obviate the need for echocardiography in one- third of stroke patients and may limit the number of secondary extracranial vascular imaging studies to approximately 10%.

Resting state functional connectivity in adolescents with bipolar I disorder

M Singh¹, R Kelley¹, L Bararpour¹, E Sanders¹, R Shoemaker¹, S Li¹, M Howe¹, A Reiss¹, K Chang¹
¹Department of Psychiatry and Behavioral Sciences, Stanford University, CA

Background: Neuroimaging studies of youth with bipolar disorder (BD) have demonstrated dysfunction in frontotemporal regions involved in emotion regulation. The goal of this study was to examine resting state functional connectivity in adolescents with BD I as compared to controls.

Methods: Adolescents (13-18 years old) with BD I (N=18) and adolescents without any personal or parental history of DSM-IV Axis I disorders (N=20) were scanned with fMRI at 3T, at rest. Group differences in resting state functional connectivity were analyzed using a Functional Connectivity Toolbox, after band-pass filtering (0.005 – 0.10 Hz) and correcting for physiological noise and motion. Regions of interest (ROIs) were defined as 10mm spheres of medial prefrontal cortex (MPFC), posterior cingulate cortex, lateral parietal cortices and 5mm spheres of nucleus accumbens. Bilateral amygdala ROIs were derived from the Automated Anatomical Labeling Atlas. ROI-to-whole-brain analyses were performed with statistical thresholds of p=0.01 for voxel height and p=0.05 Family-Wise Error (FWE) corrected for cluster extent.

Between-group comparison: Increased functional connectivity between left amygdala and superior frontal gyrus in the BD group compared to HC

Results: Relative to controls, adolescents with BD showed increased network connections between the left amygdala and superior frontal gyrus (SFG) (p=0.01 uncorrected signal and p=0.01 FWE extent). Exploratory analyses investigating medication effects of BD subjects exposed to Lithium or Valproate treatment (N=9) compared to those without exposure (N=9) displayed increased network connections from the nucleus accumbens and right amygdala with visual cortex and left parietal cortex, along with decreased connectivity between left lateral parietal (LLP) and right amygdala and nucleus accumbens (p=0.01 uncorrected signal and p=0.05 FWE extent).

Conclusions: Altered frontotemporal resting state functional connectivity in adolescents with recent onset BD suggests aberrant neural circuitry that may contribute to the pathophysiology of BD. Further studies are needed to understand how altered resting state functional connectivity in adolescents with BD-I impacts long-term clinical outcome.

Language and Reading Skills in School-Aged Children and Adolescents Born Preterm are Associated With White Matter Properties on Diffusion Tensor Imaging

HM Feldman¹, ES Lee¹, JD Yeatman², R Bammer³
Departments of ¹Pediatrics, ²Psychology, ³Radiology, Stanford University, CA

Children born preterm are at risk for deficits in language and reading and also for white matter injuries to periventricular regions of the brain. The goal of this study was to determine whether performance on language and reading measures would be associated with white matter properties in children born preterm and in full-term controls. Children born before 36 weeks gestation (n=23, mean +/- SD age 12.5 +/- 2.0 years, gestational age 28.7 +/- 2.5 weeks, birth weight 1184 +/- 431 grams) and controls born after 37 weeks gestation (n=19, 13.1 +/- 2.1 years, 39.3 +/- 1.0 weeks, 3178 +/- 413 grams) underwent a battery of language and reading tests and Diffusion Tensor Imaging (DTI). DTI scans were processed using Tract-Based Spatial Statistics to generate a core white matter skeleton that was anatomically equivalent across participants. Fractional anisotropy (FA) was the main diffusion property used in these analyses. Results showed that in the preterm group only regions of the entire skeleton were significantly associated with four tasks: verbal IQ, linguistic processing speed, syntactic comprehension, and decoding. Twenty-two clusters on 15 tracts from both the left and right hemispheres were associated language and reading measures. Exploratory multiple regression analysis found that for each task, a single brain region significantly predicted each measure, accounting between 27 and 44% of the variance in that measure. For four tasks, the region was in the right hemisphere. These findings suggest that the white matter network that serves language and reading in chil-

White Matter Language and Reading Network. White matter regions (red) on the FA-skeleton (green), overlaid on axial slices of mean FA image (grayscale), associated with at least one behavioral measure, $p < .05$, in the preterm group (n=23). Regions located on 15 tracts: corpus callosum (z = 4 – 34), forceps major (z = 4 – 16), forceps minor (z = 7 – 22), bilateral anterior thalamic radiation (z = 4 – 19), bilateral corticospinal tract (z = 4 – 37), bilateral inferior fronto-occipital fasciculus (z = 4 – 22), bilateral inferior longitudinal fasciculus (z = 4 – 7), bilateral superior longitudinal fasciculus (z = 16 – 37), and bilateral uncinate fasciculus (z = -25 – -7).

dren born preterm is widely distributed and that performance in language and reading is associated with microstructural properties of the network.

The Brain Basis of the Phonological Deficit in Dyslexia is Independent of IQ

H Tanaka^{1,2}, JM Black^{1,3,4}, C Hulme⁵, LM Stanley^{1,2}, SR Kesler^{1,3}, S Whitfield-Gabrieli⁶, AL Reiss^{1,3}, JDE Gabrieli⁶, F Hoeft^{1,3}

Although the role of IQ in the diagnosis of developmental dyslexia remains controversial, the dominant clinical and research approaches rely on a discrepancy definition requiring reading skill to be below the level expected by an individual's IQ. Here, with functional magnetic resonance imaging (fMRI), we examined whether differences in brain activation during phonological processing that are characteristic of dyslexia are similar or dissimilar in children with poor reading ability who had either high (discrepant) or low (non-discrepant) IQ scores. In two independent samples of 131 children, using univariate and multivariate pattern analyses, poor readers with discrepant or non-discrepant IQ scores exhibited similar patterns of reduced brain activation in brain regions including left parieto-temporal and occipito-temporal regions. These results converge with behavioral evidence that poor readers have similar kinds of reading difficulties in relation to phonological processing regardless of IQ.

Neural Systems Predicting Long-Term Outcome in Dyslexia

F Hoeft¹, B McCandliss², JM Black¹, A Gantman¹, N Zakerani¹, C Hulme³, H Lyytinen⁴, S Whitfield-Gabrieli⁵, GH Glover⁶, AL Reiss¹, JDE Gabrieli⁵
Departments of ¹Psychiatry and Behavioral Sciences, Center for Interdisciplinary Brain Sciences Research (CIBSR), ⁶Radiology, Stanford University, CA; ²Vanderbilt University, Nashville, TN; ³University of York, York UK; ⁴University of Jyväskylä, Jyväskylä Finland; ⁵Massachusetts Institute of Technology, Cambridge, MA

Individuals with developmental dyslexia vary in their ability to improve reading skills, but the brain basis for improvement remains largely unknown. We performed a prospective, longitudinal study over 2.5 years in children with dyslexia (N=25) or without dyslexia (N=20) to discover whether initial behavioral or brain measures, including functional MRI (fMRI) and diffusion tensor imaging (DTI), can predict future long-term reading gains in dyslexia. No behavioral measure, including widely used and standardized reading and language tests, reliably predicted future reading gains in dyslexia. Greater right prefrontal activation during a reading task that demanded phonological awareness and right superior longitudinal fasciculus (including arcuate fasciculus) white-matter organization significantly predicted future reading gains in

dyslexia. Multivariate pattern analysis (MVPA) of these two brain measures, using linear support vector machine (SVM) and cross-validation, predicted significantly above chance (72% accuracy) which particular child would or would not improve reading skills (behavioral measures were at chance). MVPA of whole-brain activation pattern during phonological processing predicted which children with dyslexia would improve reading skills 2.5 years later with over 90% accuracy. These findings identify right prefrontal brain mechanisms that may be critical for reading improvement in dyslexia and that may differ from typical reading development. Brain measures that predict future behavioral outcomes (neuroprognosis) may be more accurate, in some cases, than currently available behavioral measures.

The Use of Diffusion Tensor Imaging (DTI) in Young Children with Type 1 Diabetes

T. Aye¹, N. Barnea-Goraly², C. Ambler³, Y. Park², D. Wilson¹, A. Reiss^{2,4,5}, B. Buckingham¹
Departments of ¹Pediatrics, Division of Pediatric Endocrinology and Diabetes, ²Center for Interdisciplinary Brain Sciences Research, Psychiatry, ⁴Radiology, ⁵Department of Pediatrics, Stanford University, CA; ³Hospital Educational Advocacy Liaisons Program, Lucile Packard Children's Hospital, Stanford, CA

DTI is used to investigate white matter (WM) structure in the brain. DTI has shown deficits in WM structure in adult subjects with T1DM that correlated with reduced neurocognitive function. However, there are no published DTI studies in children with T1DM. Young children, ages 3 to 10 years, with T1DM and matched healthy controls (HC) completed age appropriate batteries of neuropsychological tests and MRI scans of the brain. Twenty-one DTI scans from children with T1DM (mean age 7.9 ± 1.6) and 12 scans from HC (mean age 7.3 ± 1.6) were analyzed using Tract-Based Spatial Statistics (TBSS). Voxel-wise between-group comparisons of Fractional Anisotropy (FA, degree of diffusion anisotropy), Radial Diffusivity (RD, representing diffusion perpendicular to the fiber axis) and Axial Diffusivity (AD, representing diffusion along the fiber axis) were performed using Threshold-Free Cluster Enhancement in a fully corrected analysis. We used TBSS to conduct correla-

tion analysis between WM structure and HbA1C levels, duration of T1DM, and neuropsychological test scores. Using a whole-brain analysis, there were no significant differences between T1DM and HC. Negative correlations of FA (p = 0.053) and RD (p = 0.055) with increased HbA1c in the internal capsule and splenium of the corpus callosum approached significance. A negative trend was seen between FA and NEPSY attention scores (0.09) in the fronto-striatal tracts which are known to be related to attention. These tracts were used in a post-hoc analysis as a region of interest to investigate whether attention-related circuits are affected in T1DM. In this analysis, significantly reduced AD was seen in T1DM when compared to HC (p = 0.04). This is the first study to suggest early signs of WM variation in children with T1DM. Larger studies of WM structure are needed to define the impact of T1DM on the developing brain.

Neuroimaging & fMRI

Effects of duloxetine and placebo in patients with chronic low back pain

KA Johnson, N Chatterjee, N Noor, A Crowell, R McCue, S Mackey
Department of Anesthesia, Stanford University, CA

Chronic low back pain has a tremendous impact and is difficult to treat. Duloxetine is a serotonin-norepinephrine reuptake inhibitor used for a variety of indications, including depression, diabetic peripheral neuropathy, and fibromyalgia. Recent studies suggest that duloxetine may have efficacy in treating chronic lower back pain. In a randomized, double-blind, placebo-controlled crossover study, we used clinical assessments to examine the effects of duloxetine and placebo. Additionally, we used MRI to detect possible brain effects of duloxetine and placebo. Patients with at least 6 months of back pain (no radicular symptoms), a minimum 4/10 pain rating for two weeks prior to enrollment, and no current pain medication use (except acetaminophen) were eligible to enter the study. Duloxetine administration was 30mg/day for one week, followed by 60mg/day for five weeks. Placebo administration and assessment were identical to duloxetine administration. Clinical assessments occurred at baseline, and at

weeks 1, 2, and 6 into each medication period. Week 6 was the crossover point, where patients were switched to duloxetine or placebo. Additional at-home measures were collected. Clinical measures included basic medical assessments, a battery of pain related questionnaires, and mood and depression ratings. Data collection was completed in 18 patients. Preliminary analysis indicates a significant change in pain ratings at the end of the duloxetine period, particularly for patients who received placebo first. Most patients had minimal to mild depression (BDI < 19) upon study enrollment. A few patients entered the study with moderate or severe depression, which decreased with duloxetine and placebo treatment. Preliminary structural MRI indicated changes in gray matter with both duloxetine and placebo, including increases in frontal cortex regions. Initial analysis indicates that duloxetine has brain and behavioral effects for chronic low back pain patients.

Central sensitization in the human spinal cord as measured with functional magnetic resonance imaging

PG Nash, JE Brown, SC Mackey
Department of Anesthesia, Stanford University, CA

Central sensitization, which involves an increased gain in the nociceptive system, has received growing support as a possible mechanism underlying chronic pain conditions. The heat-capsaicin model has been shown to reliably evoke symptoms of chronic pain such as secondary mechanical hyperalgesia (SMH). In experimental animals, SMH has been shown to result from central sensitization within the dorsal horn of the spinal cord, however the difficulties associated with imaging the spinal cord has mean that this is yet to be confirmed in humans. The aims of this study are to determine the activation patterns in the spinal cord due to mechanical stimuli in an experimentally induced model of central sensitization. Following the establishment of heat-capsaicin model on the volar forearm, a continuous series of fMRI brain images (212 spiral in out, gradient echo volumes, voxel size=1.25x1.25x4mm, TR=2.5seconds) were collected over a 9minute period. The scan began with a 40 second baseline followed by 30 seconds of mechanical stimulation the site of SMH, this was repeated 7 times. The contra-

lateral-untreated side was stimulated identically in the same location to serve as a control. Images were converted and retrospectively corrected for heart rate and respiratory motion using RETROICor software. Additional motion correction was made using Art_Repair software. Images were realigned, normalized and smoothed (3mm full width half maximum (FWHM)) using SPM8. Changes in signal intensity were determined using a box-car model convolved with a haemodynamic response function (random-effects procedure; uncorrected) Results revealed an increase in spinal BOLD activation on the side ipsilateral to painful allodynic brushing. Furthermore this was found to be anatomically appropriate to the dermatome stimulated. These results demonstrate our ability to image the effects SMH as generated by the heat-capsaicin model. This indicates the possibility of imaging central sensitization in the spinal cord in pathological pain conditions.

Neural Effects of Systemic Lidocaine on Chronic Neuropathic Pain Patients

H Ung, S Mackey, N Chatterjee, M Tieu, R Moericke, I Carroll
Department of Anesthesia, Stanford University, CA

Millions of Americans with neuropathic pain also present with mechanical allodynia, in which normally innocuous stimuli elicits pain. Sodium channel blockers such as lidocaine have shown efficacy in attenuating the painful sensation, though the specific changes that occur within the central nervous system remain ambiguous. This study aims to elucidate the mechanism of analgesic response prompted by systemic lidocaine through the use of functional magnetic resonance imaging (fMRI). Chronic pain patients (N = 8) with mechanical allodynia provided written and informed consent according to protocols approved by the Stanford Institutional Review Board. Functional MRI scans were conducted at a Stanford University 3 Tesla GE scanner using a standard block design where the stimulus was brushing of the allodynic area under 3 conditions: baseline, saline placebo, and lidocaine. Brushing of an unaffected area under baseline conditions was used as a control. A fixed effects, general linear model analysis was performed using SPM8. We found increased activity in prefrontal areas and de-

creased activity in the amygdala and hippocampal regions in conditions of lidocaine versus placebo. In addition, systemic lidocaine reduced activity in the primary sensory cortex, supplemental motor area, and putamen. Although lidocaine is a nonspecific sodium channel blocker and sodium channels are ubiquitous throughout the nervous system, these results indicate that lidocaine influences specific regions of the brain. The exact mechanism remains unclear, and further analysis and data are required to improve our understanding of the analgesic effects of lidocaine.

White Matter Characteristics Associated with Attention, Anxiety, & Executive Function in Preterm Adolescents

ES Lee¹, IM Loe¹, JD Yeatman², R Bammer³, HM Feldman¹
Departments of ¹Pediatrics, Division of Neonatal and Developmental Medicine, ²Psychology, ³Radiology, Stanford University, CA

Adverse outcomes of children born preterm include increased rates of inattention and anxiety and poor executive function skills. Prematurity is associated with injury to the white matter tracts of the brain. Diffusion Tensor Imaging (DTI) is a magnetic resonance imaging technique that provides quantitative characterization of white matter tracts. This study used DTI to compare white matter characteristics in children and adolescents born preterm and full-term and to examine the degree of association between fractional anisotropy of white matter and three outcomes: attention problems, anxiety symptoms, and executive-function impairment. Participants were 9 to 16 years of age; 23 were born at less than 36 weeks gestation (mean = 28.7 weeks, birth weight = 1184 grams) and 19 were full-term. Outcome measures included parent-rated attention problems and anxiety symptoms and objective measures of executive function. We analyzed the results using Tract-Based Spatial Statistics, a technique that generates a skeleton representing the core

unfavorable scores were consistently associated with lower FA. Thirty-four regions on 10 tracts were associated with all three outcomes, indicative of distributed and shared mapping. However, for each of the functions, only one to three tracts and age accounted for 35 to 52% of the variance in scores. For each function, at least one of these tracts coursed into the frontal lobes. DTI contributes to understanding individual differences in attention, anxiety, and executive function in children and adolescents born preterm and full-term.

Fractional anisotropy along the trajectory of selected white matter tracts in adolescents born preterm with ventricular dilatation

NJ Myall¹, KW Yeom², JD Yeatman³, S Gaman-Bean⁴, R Bammer², HM Feldman⁴
Departments of ¹School of Medicine, ²Radiology, ³Psychology, ⁴Pediatrics, Stanford University, CA

The aim of this study was to assess the microstructural characteristics of white matter tracts in adolescents born preterm with non-shunted ventricular dilatation secondary to intraventricular hemorrhage. Three adolescents born preterm with ventricular dilatation (ages 12-17 years, gestational age [GA] 26-29 weeks, birth weight [BW] 825-1624 grams) were compared to three full-term controls (ages 14-17 years, GA 39-40 weeks, BW 3147-3345 grams) and three adolescents born preterm without ventricular dilatation (ages 10-13 years, GA 26-29 weeks, BW 630-1673 grams). Tractography was performed using a two region-of-interest method for the following white matter tracts: superior longitudinal fasciculus/arcuate fasciculus, inferior longitudinal fasciculus, inferior fronto-occipital fasciculus, uncinate fasciculus and corticospinal tract. The mean fractional anisotropy, axial diffusivity and radial diffusivity of each fiber tract were calculated. Fractional anisotropy was also calculated

at 30 equidistant segments along each tract. Subjects with moderate ventricular dilatation showed increased fractional anisotropy compared to the other two groups in multiple bilateral tracts. The pattern of fractional anisotropy along the trajectory of tracts adjacent to the lateral ventricles distinguished preterms with ventricular dilatation from full-term controls and preterm comparisons. By contrast, the pattern of fractional anisotropy along the uncinate fasciculus did not vary between groups. Prematurity is often associated with decreased fractional anisotropy. Our findings suggest that concomitant ventricular dilatation may have opposing effects on fractional anisotropy possibly secondary to increased packing density of axons.

Anticipatory hippocampal responses predict individual differences in reward-based modulation of memory

SM Wolosin, D Zeithamova, AR Preston
The University of Texas at Austin, Austin, TX

Emerging evidence suggests that medial temporal lobe (MTL) memory processing is modulated by reward, resulting in enhanced encoding of episodic information—long-term memory for events. Recent neuroimaging research has further revealed activation in hippocampus prior to stimulus presentation that predicts later memory performance, suggesting that modulatory processes such as reward may influence encoding processes in anticipation of upcoming events. Moreover, individual differences in neural responses to reward predict performance in reinforcement learning paradigms. Such individual differences in reward sensitivity may similarly influence the degree to which reward impacts MTL encoding. Using high-resolution functional magnetic resonance imaging (fMRI), the present study examines (1) how cues indicating future rewards influence MTL subregional activation prior to associative encoding and (2) how individual differences in reward sensitivity are reflected in MTL

subregional activation. A high-value or low-value monetary cue preceded a pair of objects indicating potential reward for successful retrieval of the association. Memory was tested using a two-alternative forced-choice paradigm. Behaviorally, memory was superior for high-value associations relative to low-value associations. fMRI analysis revealed anticipatory responses within the hippocampus predicting memory formation that were further modulated by reward. Importantly, the observed enhancement of anticipatory activation for high-value compared to low-value pairs correlated with individual differences in behavioral reward sensitivity (hit rate for high-value pairs – hit rate for low-value pairs). The results suggest that reward-based motivation influences memory by facilitating hippocampal encoding processes prior to stimulus presentation, and that increased behavioral sensitivity to reward is reflected by increases in reward effects within the hippocampus.

Motivation during associative encoding influences subsequent recall responses in medial temporal subregions

SM Wolosin, D Zeithamova, AR Preston
The University of Texas at Austin, Austin, TX

Emerging evidence suggests that hippocampal memory processing is modulated by reward, resulting in enhanced encoding of episodic information—long-term memory for events. Current theories further propose that memory processing in hippocampal subregions may be differentially influenced by reward. While previous research has examined reward influences on episodic encoding, no study to date has examined how motivation during encoding influences hippocampal responses at retrieval. Using high-resolution functional magnetic resonance imaging (fMRI), the present study investigated the function of medial temporal lobe (MTL) subregions, including hippocampal subfields, midbrain, and nucleus accumbens during cued recall of associations learned under varying conditions of reward. During encoding, high-value or low-value monetary cues preceded object pairs indicating potential reward for successful retrieval of the associations. At retrieval, participants were presented with a cue object (a single object from a studied pair) and were asked to recall and imagine the associated object during a delay period. At the end of the trial, participants viewed a probe object and judged whether the probe was the correct object (a “match”) or another object viewed at encoding, but as part

of a different pair (a “mismatch”). Behaviorally, cued recall performance was superior for high-value compared to low-value pairs. fMRI analysis revealed regions in hippocampus, including dentate gyrus/CA2,3, CA1, and subiculum, as well as parahippocampal cortex and nucleus accumbens that demonstrated greater cue and delay period activation for high-value compared to low-value associations. Importantly, such reward-based modulation of cue and delay period activation was observed in the absence of explicit reward cues. Of these regions, left CA1 uniquely showed an interaction between reward status and retrieval based success effects where activation differed for correct and incorrect trials only for high-value associations. At probe, several MTL regions demonstrated match responses with greater activation for correct match probes relative to correct mismatch probes. In these probe-sensitive regions, match effects in left CA1 and left dentate gyrus/CA2,3 were limited to high-value trials. Together these findings suggest that motivation during encoding affects subsequent associative retrieval processing in MTL subregions, and highlight that within the hippocampus CA1 may play an important role incorporating motivational salience into episodic retrieval processes.

Population receptive fields in human visual cortex measured with subdural electrodes

J Winawer¹, AM Rauschecker¹, KN Kay¹, J Parvizi², BA Wandell¹
Departments of ¹Psychology, ²Neurology & Neurological Sciences, Stanford University, CA

PURPOSE. Population receptive fields (pRFs) in human visual cortex have been measured with fMRI (Dumoulin and Wandell, 2008; Kay et al., 2008) and with electrocorticography (ECoG) in pre-surgical clinical subjects (Yoshor et al, 2007). We present an efficient method for pRF measurements using ECoG, closely matched to the fMRI methods developed by Dumoulin and Wandell (2008), and we compare the results to those obtained with fMRI. **METHODS.** Three patients with intracranial electrodes (2-mm diameter) viewed flickering contrast patterns through a bar aperture that swept across the visual field 8 times (96 seconds). For one subject, bar width varied across experiments to test response linearity. The contrast pattern reversed 15 times / s, creating a steady-state ECoG response at this frequency. Time-series were extracted in the steady-state (15-Hz) and gamma-band (30 Hz - 180 Hz) to estimate the spatial pRF, modeled as an isotropic 2D-Gaussian. **RESULTS.** The pRF model provided good fits to the steady-state and gamma-band time-series of V1, V2, and V3 electrodes. The position and size

parameters of the pRFs were similar to those obtained from fMRI in the same subjects. However the steady-state ECoG data differed markedly from the gamma-band and fMRI data in one respect: as bar width increased, the steady-state signal amplitude systematically increased, whereas the gamma-band and fMRI signals saturated. Consequently, the steady-state data were well fit by a linear model whereas the fMRI and gamma-band data were better fit by a model with a saturating non-linearity. **CONCLUSION.** There is good agreement between fMRI and ECoG pRFs despite significant differences in their physiological bases. The agreement is best in the gamma band, which, like the fMRI measures, contains a saturating non-linearity. ECoG provides a valuable complement to fMRI for probing population-level spatiotemporal properties of receptive fields in human visual cortex.

Thalamo-cortical connectivity distinguishes painful from non-painful stimulation in humans

J Brown, N Chatterjee, S Mackey
Department of Anesthesia, Stanford University, CA

Neuroimaging studies reveal a distributed network of brain regions activated by painful stimulation, suggesting that the subjective experience of pain depends not only on the activity within individual brain regions, but also on their interactions. A recent study showed pre-stimulus interactions among pain-related brain areas were associated with pain perception in humans. However, it remains largely unknown how interactions among brain regions during pain perception are related to subjective aspects of the pain experience. We address this issue using fMRI to correlate activity among several brain regions during the perception of painful and non-painful thermal stimulation. We hypothesized that brain regions previously implicated in pain interact with each other differently during the perception of pain than during the perception of non-painful thermal stimulation. We presented painful and non-painful stimuli to the left forearm and recorded BOLD signal change from each region of the canonical pain matrix: primary and secondary sensory cortices (S1 and S2), thalamus, prefrontal cortex (PFC), insular cortex (IC), and anterior cingulate cortex (ACC). For each stimulus presented we computed the average BOLD signal change that resulted as a percentage of the preceding baseline period. We then computed pair-wise correlations of the BOLD signal change in each region during each stimulus presentation. A stronger correlation between two regions during painful than non-painful stimulation might indicate that the two regions are each receiving more similar inputs during painful stimulation or that one is influencing the other in a more consistent manner during periods painful than non-painful stimulation We found that pair-wise correlations including thalamus-S1, thalamus-S2, thalamus-IC, and thalamus-ACC were significantly greater during painful stimulation than during non-painful stimulation. Our findings demonstrate that pain processing is associated with strong thalamo-cortical interactions. It is important to determine how these interactions relate to pain ratings, fear of pain, and anxiety.

Differences in neural activation between preterm and full term born adolescents on a sentence comprehension task: Implications for educational accommodations

LHF Barde¹, JD Yeatman², ES Lee¹, G Glover³, HM Feldman¹
Departments of ¹Pediatrics, ²Psychology, ³Radiology, Stanford University, CA

This fMRI study compared patterns of neural activation during a sentence comprehension task in children born preterm (n = 18) and full-term (n = 14), and described patterns associated with individual differences. Participants (approximately 10-16 years) were matched across group for verbal IQ and receptive vocabulary. Both groups showed bilateral activation in superior and middle temporal gyri comparing sentence comprehension to fixation during the initial Auditory phase of the task. The preterm group showed greater activation in the precuneus when processing syntactically difficult sentences. Patterns of activation shifted for both groups in the Verification/Response phase of the task. There, the preterm group showed greater activation in the left middle frontal gyrus than did the full-term group when processing syntactically difficult sentences, controlling for receptive language ability. The results suggest that in comparison to full-term peers, the preterm group showed greater

activation in an area associated with cognitive control when processing difficult material despite comparable performance. These findings, in conjunction with other features of children born preterm, such as weak executive function skills, high rates of inattention, and elevated anxiety symptoms, suggest the importance of considering the child’s early medical history and neurological status in education.

Default-mode and task-positive network activity in Major Depressive Disorder: Implications for adaptive and maladaptive rumination

JP Hamilton¹, D Furman¹, C Chang², M Thomason³, E Dennis³, I Gotlib³
Departments of ¹Psychology, ²Radiology, ³Psychology, Stanford University, CA

Background. Major Depressive Disorder (MDD) has been associated reliably with ruminative responding, which can involve both maladaptive and adaptive components. Levels of activity in the default-mode network (DMN) relative to the task-positive network (TPN), as well as activity in structures that influence DMN and TPN functioning, may represent important neural substrates of maladaptive and adaptive rumination in MDD. **Methods.** We used a unique metric to estimate DMN dominance over TPN from blood-oxygen-level dependent (BOLD) data collected during eyes-closed rest in 17 currently depressed and 17 never-disordered adults. We calculated correlations between this metric of DMN dominance over TPN and the depressive, brooding, and reflective subscales of the Ruminative Responses Scale, controlling for associations both among these measures and between these measures and severity of depression. Finally, we estimated and compared between groups right fronto-insular cortex (RFIC) response during initiations of ascent in DMN and TPN activity. **Results.** In the MDD participants, increasing levels of DMN dominance were associated with higher levels of maladaptive, depressive rumination and lower levels of adaptive, reflective rumination (see Figure 1). Moreover, the RFIC state-change analysis showed increased RFIC activation in the MDD participants at the onset of increases in TPN activity and, conversely, increased RFIC activation in the healthy control participants at the onset of increases in DMN activity. **Conclusions.** These findings provide empirical evidence for a formulation in which the DMN supports the representation of negative, self-referential information in MDD, and the RFIC, when prompted by increased levels of DMN activity, initiates an adaptive engagement of the TPN.

Fast Susceptibility Weighted Imaging (SWI) using Readout-Segmented (RS)-EPI

SJ Holdsworth¹, RL O'Halloran¹, S Skare², R Bammer¹
¹Department of Radiology, Stanford University, CA; ²Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden

Introduction: Susceptibility-weighted imaging (SWI) is an MRI technique that has been used to provide improved conspicuity of venous blood vessels and other sources of susceptibility effects. The most commonly used SWI acquisition uses a 3D gradient echo (GRE) sequence, however due to the inefficient coverage of k-space per TR, 3D GRE is hampered by a long scan time. In addition, even subtle motion in 3D GRE can considerably hamper the quality of final processed SWI image. Here we explore the use of 3D Readout-Segmented (RS)-EPI as a fast alternative to 3D GRE for SWI. In RS-EPI, a ‘brick’ made up of several adjacent (and slightly) overlapping EPI segments are acquired.

Methods: 3D RS-EPI and 3D GRE data were acquired on a healthy volunteer using a 3T GE system and an 8-channel head coil. The SWI images were produced by generating a phase mask using a 2D Hanning window for each individual coil, a multiplica-

tion of the phase mask by the magnitude coil by 5 times, followed by the sum of squares over coils.

Results: A comparison between the SWI images acquired with 3D GRE and 3D RS-EPI is shown in the figure. Although the resolution and SNR is highest for the 3D GRE, the 3D RS-EPI images show it is possible to acquire good quality SWI images with twice the brain coverage in about a third of the scan time.

Conclusion: The acquisition of 3D RS-EPI SWI images in 1:15min makes this technique applicable for routine use in the clinics and a fast alternative to 3D GRE. The inherent motion robustness of 3D RS-EPI is another major advantage of RS-EPI over both GRE and interleaved EPI. As long as the brick frame rate in 3D RS-EPI is fast enough and there is enough overlap between bricks, it should be possible to correct for motion between bricks in k-space in 3D.

Evaluating airfoil trailing edge film cooling geometries based on 3D velocity and scalar field measurements

M Benson, C Elkins, J Eaton
Department of Mechanical Engineering, Stanford University, CA

The high temperature blades and vanes in gas turbine engines are cooled by passing cooler air through their interiors and venting it through holes in their surfaces. The effectiveness of this approach is governed by the rate of mixing of the coolant with the mainstream flow. One important region of interest is the thin trailing edge of a blade or vane airfoil which is particularly vulnerable to melting. Ideal cooling results in a uniform distribution of 100% coolant over the entire trailing edge surface. In this study, several different trailing edge cooling geometries were evaluated for cooling effectiveness. Coolant concentration was measured using the Magnetic Resonance Concentration (MRC) technique which uses a T1 weighted imaging sequence to measure the mixing of a contrast solution with plain water. The scans measured the concentration distribution with a spatial resolution of 0.5 mm3 and an uncertainty near 5%. 3D phase contrast measurements were made to provide 3D, mean velocity measurements in the identical flow. The coupled concentration and velocity measurements were used to understand the relationship between geometrical features, flow structures, and cooling effectiveness. Improved geometries increased the spanwise averaged coolant concentration at the trailing edge by as much as 15% and improved the spanwise distribution uniformity.

Flow separation control in a conical diffuser with an annular inlet

K Lo, C Elkins, J Eaton
Department of Mechanical Engineering, Stanford University, CA

In a combined cycle power plant, the high velocity exhaust from the power turbine has to be slowed down before reaching the steam generator. A conical diffuser is commonly used behind the turbine to slow down the flow and recover pressure. The inlet to the diffuser is an annulus due to the annular flow passage of the turbine. A large central separation bubble forms if the central hub ends abruptly because the flow is incapable of negotiating around a sharp corner. Previous experiments demonstrate that a Coanda jet at the end of the hub can strongly reduce or completely eliminate the central separation bubble, depending on the jet blowing ratio. However this can cause flow separation along the conical diffuser walls in some cases. A backward facing step in the outer diffuser wall acts to fix the location of separation making it more amenable

to control. A single circumferential separation bubble forms downstream of the step. Experiments were performed in scaled down diffuser models to investigate a geometric perturbation approach for reducing the size of the step separation bubble. The Reynolds number is 64000 based on the annulus bulk velocity and hydraulic diameter. Full-field, three-component velocity data were measured in a series of diffuser models using phase contrast magnetic resonance velocimetry. The step separation bubble is around eight step-heights long when no control is present. A wavy step edge design, where the separating edge of the step is a sinusoid, significantly reduces the size of the bubble by almost 50%. The single circumferential bubble is broken down into a series of smaller bubbles. Velocity data reveal pairs of counter-rotating in-plane vortices, which are responsible for the bubble size reduction by enhanced momentum mixing.

Common abnormalities and disorder-specific compensation in anxiety versus depression

A Etkin^{1,2}, AF Schatzberg¹
¹Department of Psychiatry and Behavioral Sciences, Stanford University, CA; ²Sierra-Pacific Mental Illness Research, Education, and Clinical Center (MIRECC) Veterans Affairs Palo Alto Health Care System

Objective: Anxiety and depressive disorders are both associated with abnormalities in the processing and regulation of emotion. Despite this, little is known about the similarities and differences between anxiety and depression at the neural level. Such research is essential, however, for understanding the organization and structure of mental illness, informing ideas about vulnerability, and defining opportunities for intervention.

Methods: 32 healthy controls, 18 generalized anxiety disorder only patients, 14 major depression only patients, and 25 comorbid patients were studied using functional magnetic resonance imaging while they performed an emotional conflict task, which involved categorizing facial affect while ignoring overlaid affect label words. We compared trial-by-trial changes in conflict regulation, a test of implicit regulation of emotional processing, using behavioral and neural measures.

Results: Behavioral data indicated that only patients with generalized anxiety (i.e. anxiety only and comorbid) failed to implicitly regulate emotional conflict. By contrast, deficits in activation and connectivity of the ventral anterior cingulate and amygdala – areas previously implicated in regulating emotional conflict – were found in all patient groups. Depression only patients, however, compensated for this deficit by also activating bilateral anterior lateral prefrontal cortices, wherein activity correlated with behavioral evidence of successful implicit regulation, thus mediating the disorder-specificity of the behavioral phenotype.

Conclusions: These data support the existence of a common anxiety/depression ventral cingulate-amygdalar abnormality, which may relate to a shared genetic etiology. Compensatory engagement of cognitive control circuitry in depression illustrates how the complex nature of psychopathology arises from the interaction of deficits and compensation, all of which can occur at an implicit level.

fMRI Imaging of Opioid Withdrawal in Healthy Human Volunteers

LF Chu¹, D Hoang¹, X Cui², A Clemenson¹
Departments of ¹Anesthesia, ²Center for Interdisciplinary Brain Sciences Research, Stanford University, CA

Background: Opioid medications are commonly prescribed for pain relief. When given over an extended period, physical dependence can develop. If opioid medications are suddenly stopped, opioid withdrawal occurs with unpleasant side effects, such as agitation and nausea. A medication named ondansetron can help ease or prevent these symptoms. Though the physical symptoms and treatment of opioid withdrawal have been extensively studied, it is still unknown how withdrawal affects brain activity. Through imaging of the brain by fMRI, we hope to see how opioid withdrawal, with and without the administration of ondansetron, affects brain activity.

Methods: Healthy male volunteers were randomized to receive ondansetron on one of two study days and placebo on the other. After the administration of placebo or ondansetron, patients received an infusion of morphine. Patients were transported to the Lucas Center, where they underwent a 24-minute fMRI scan. After 9 minutes of baseline scanning, patients were given an injection of Naloxone to precipitate withdrawal. Patients remained in the scanner for 15 minutes and were then transported back to the hospital.

Results: Our research is still in progress, but preliminary data has shown that there were significant positive and negative changes in brain activity during opioid withdrawal when the patients had only placebo treatment. When patients received ondansetron, there was very little positive or negative change.

Conclusion: Our research is still ongoing, but preliminary data suggests that ondansetron has a dampening effect on the positive and negative changes in brain activity. We are currently researching and analyzing these brain areas of interest.

Altered frontostriatal functional connectivity in Major Depressive Disorder

DJ Furman, JP Hamilton, IH Gotlib
Department of Psychology, Stanford University, CA

Dysfunction of the striatum and frontal cortex has been reported consistently in studies of neural structure and function in Major Depressive Disorder (MDD). Despite speculation that compromised connectivity between these regions may underlie symptoms of MDD, little work has investigated the integrity of frontostriatal circuits in this disorder. In this study we compared patterns of resting state frontostriatal functional connectivity in currently depressed and never-disordered women. Blood-oxygen-level dependent (BOLD) data were acquired from 21 currently depressed individuals and 19 healthy controls during eyes-closed, wakeful rest in a 3T GE scanner. Using four predefined regions of interest, we computed seed-to-whole brain correlations. We found that, compared to controls, depressed participants exhibited attenuated functional connectivity between the ventral striatum and both ventromedial prefrontal cortex and subgenual cingulate cortex. Depressed participants also

depression, and the extent to which these patterns normalize with remission of depressive illness.

Functional connectivity tracks clinical deterioration in Alzheimer’s disease

JS Damoiseaux¹, K Prater², BL Miller³, MD Greicius¹
¹Functional Imaging in Neuropsychiatric Disorders (FIND) Lab, Department of Neurology and Neurological Sciences, Stanford University, CA;
²Neuroscience Graduate Program, University of Michigan, MI; ³Memory and Aging Center, Department of Neurology, University of California, San Francisco, CA

While resting state functional connectivity has been shown to decrease in patients with mild/moderate Alzheimer’s disease, it is not yet known how functional connectivity changes in patients as the disease progresses. Furthermore, it has been noted that the default mode network is not as homogenous as previously assumed and several fractionations of the network have been proposed. Here, we separately investigated the modulation of three default mode sub-networks, as identified with group ICA, by comparing Alzheimer’s disease patients to healthy controls and by assessing connectivity changes over time. Our results showed decreased connectivity at baseline in patients versus controls in the posterior default mode network, and increased connectivity in the anterior and ventral default mode networks (see figure). At follow-up, functional connectivity decreased across all default mode systems in patients. Our results suggest that earlier in the disease, regions of the posterior default mode network start to disengage whereas regions within the anterior and ventral networks enhance their connectivity. However, as the disease progresses connectivity within all systems eventually deteriorates.

Compressive spatial summation improves models of extrastriate responses

KN Kay¹, J Winawer¹, A Mezer¹, BA Wandell¹
¹Department of Psychology, Stanford University, CA

Integrating image features across space is fundamental to visual function. Previous fMRI studies investigating retinotopy and related spatial properties have assumed implicitly or explicitly that responses to spatial contrast patterns sum linearly over the visual field. To test this assumption, we measured BOLD activity in human visual cortex while subjects viewed brief presentations of contrast patterns seen through horizontal and vertical apertures. A variety of different apertures were presented in random order in an event-related design. Throughout visual cortex the response to a large aperture was less than the sum of the responses to two parts of the aperture shown in separate trials. This sub-additive effect was larger in extrastriate areas than in V1. We modeled the sub-additivity by incorporating a compressive power-law nonlinearity into a basic linear model of population receptive fields (Dumoulin and Wandell, 2008; Kay et al., 2008). Using cross-validation to obtain

unbiased measures of model accuracy, we found that the nonlinear model systematically outperforms the linear model, explaining up to 98% of the variance in the amplitudes of the responses to the various apertures. Moreover, the nonlinearity of the model was more pronounced in extrastriate areas, consistent with the larger degree of sub-additivity in these areas (for instance, in L/O-1 the median exponent was 0.05 whereas in V1 the median exponent was 0.35). An important prediction of compressive spatial summation is reduced sensitivity to changes in the position and size of a viewed object. Indeed, in an independent dataset we measured responses to objects varying in position and size and confirmed that the nonlinear model (but not the linear model) accurately predicts the pattern of responses from each voxel. We speculate that compressive spatial summation is a key computation used by extrastriate cortex to achieve position and size tolerance.

Detection of sequence violations in the medial temporal lobe: Subregional contributions to memory-based prediction through high-resolution fMRI

JC Liang, D Zeithamova, AR Preston
The University of Texas at Austin, Austin, TX

Current research proposes that medial temporal lobe (MTL) subregions perform distinct computations to enable comparison between past and present experience. Hippocampus is thought to play a unique role in the detection of sequence novelty, wherein associated items appear in a new order. However, it is unclear how hippocampal subregions and surrounding MTL cortex differentially contribute to novelty detection, and whether content-sensitive networks are differentially engaged when novelty is restricted to a certain class of content. Here, we used high-resolution fMRI to measure MTL responses to temporal sequence violations while subjects performed an incidental 1-back detection task. Trials consisted of two consecutive sequence presentations. In the first, participants observed a sequence of four object-scene pairs. In the second presentation, the same set of object-scene pairs were presented again in one of six conditions. In the repeated condition, the initial sequence was repeated in the same order. In the half condition (H), the order of the third and fourth object-scene pairs was switched. In the object-half (OH) condition, the order of objects in the third and fourth pair was switched. In the scene-half (SH) condition, the order of scenes was switched. In the novel (N) condition, the order of all four objects and

scenes was scrambled. Finally, a familiar condition consisted of pre-exposed sequences seen repeatedly throughout the experiment. By comparing activation during the half conditions with novel sequences, we isolated responses that reflect novelty responses cued by a violation of expectation based on temporal order (a mismatch) from novelty responses that reflect novel associations per se. Furthermore, comparison of OH, SH, and novel sequences sought to reveal MTL regions that signal content-based mismatch responding. Preliminary analyses identified distinct populations of voxels that were sensitive to violations of object order (OH > N) and violations of scene order (SH > N) as well as voxels that were sensitive to violations based solely on overall temporal order (H > N). These associative mismatch responses were primarily restricted to hippocampal subfields. By contrast, MTL cortical regions showed sensitivity to novelty that was predominantly related to the amount of previous exposure when comparing novel to highly familiar sequences. These results expand on previous findings to suggest that hippocampal responses to associative novelty can be distinguished by the class of content being violated, and that MTL cortical regions show sensitivity to the familiarity status of stimulus configurations based on the amount of exposure.

Reduced hippocampal activity during encoding in cognitively normal adults carrying the APOE ε4 allele

M Adamson^{1,2}, JB Hutchinson³, A Shelton⁴, AD Wagner³, JL Taylor^{1,2}
¹Department of Veterans Affairs, Sierra-Pacific MIRECC and WRIISC Palo Alto, CA; Departments of ²Psychiatry and Behavioral Sciences, ³Psychology, Stanford University, CA; ⁴Department of Psychological and Brain Sciences, John Hopkins University, Baltimore, MD

Apolipoprotein (APOE) ε4-related differences in memory performance have been detected before age 65. The hippocampus and the surrounding medial temporal lobe (MTL) structures are the first site affected by Alzheimer’s disease (AD) and the MTL is the seat of episodic memory, including visuo-spatial memory. While reports of APOE ε4-related differences in these brain structures are not consistent in either cross-sectional or longitudinal structural and functional magnetic resonance imaging (fMRI) studies, there is increasing evidence that brain activity at baseline (defined as activity during fixation or rest) may differ in APOE ε4 carriers compared to non-carriers. In this fMRI study, cognitively normal APOE ε4 carriers and non-carriers engaged in a perspective-dependent spatial learning task (Shelton and Gabrieli, 2002) previously shown to activate MTL structures in older participants (Borghesani et al., 2008). A low-level, visually engaging dot-control task was used for comparison, in addition to fixation. APOE ε4

carriers showed less activation than non-carriers in the hippocampus proper during encoding. Specifically, when spatial encoding was contrasted against the dot-control task, encoding-related activation was significantly lower in carriers than non-carriers. By contrast, no ε4-related differences in the hippocampus were found when spatial encoding was compared with fixation. Lower activation, however, was not global since encoding-related activation in early visual cortex (left lingual gyrus) was not different between APOE ε4 carriers and non-carriers. The present data document APOE ε4-related differences in the hippocampus proper during encoding and underscore the role of low-level control contrasts for complex encoding tasks. These results have implications for fMRI studies that investigate the default-mode network (DMN) in middle-aged to older APOE ε4 carriers to help evaluate AD risk in this otherwise cognitively normal population.

The impact of age-related brain changes on flight simulator performance and decision-making

M Adamson^{1,2}, D Heraldez², M Farrell¹, Q Kennedy², J Yesavage^{1,2}, JL Taylor^{1,2}
¹Department of Veterans Affairs, Sierra-Pacific MIRECC and WRIISC, Palo Alto, CA; ²Department of Psychiatry and Behavioral Sciences, Stanford University, CA

Age-related decline in cognitive abilities and brain structures, crucial for aircraft navigation and decision making, may lead older pilots to perform poorly in a flight simulator task and can also influence their decision-making abilities. Studies also report the compensatory role of expertise in cognitive decline. We previously reported an interaction of brain size with aviation expertise in predicting flight simulator performance. We also reported that older pilots were more likely than younger pilots to take risks during landing in

bad weather. These findings led to our current study that evaluates the role of age-related changes in the brain during the decision-making network during performance of a real-world skilled task: a pilot’s crucial decision to land or not under difficult weather conditions. Understanding how older adults make crucial time-pressured real-world decisions, in relation to acquired expertise and age-related brain changes, have implications for their assessment of risk and safety in every-day life.

High-resolution fMRI reveals distinct forms of associative novelty responding in hippocampus

C Manthuruthil, D Zeithamova, A Preston
The University of Texas at Austin, Austin, TX

Hippocampal responding is greater when encountering novel relative to repeated events. Novelty, however, can take several forms, e.g., discrimination of never-before-seen stimulus combinations (associative novelty per se) or stimulus configurations that violate existing memories (associative mismatch novelty), to support distinct learning processes. Previous research suggests that signals reflecting associative novelty per se predict binding of information within individual events, whereas associative mismatch responses have been implicated in integrative encoding where information is bound across discrete episodes. By comparing hippocampal activation across repetitions of non-overlapping object associations (XY) with those elicited by overlapping associations (AB, BC), we aimed to isolate distinct forms of associative novelty responding within hippocampus using high-resolution fMRI. We hypothesized that hippocampal activation would differ for non-overlapping and overlapping associations, with decreasing hippocampal activation across repetition

of non-overlapping pairs, reflecting decreasing novelty of the associations, and increasing hippocampal activation across repetition of overlapping associations, reflecting enhanced associative mismatch detection as memories are established. Consistent with these predictions, we observed two distinct novelty signatures within hippocampus. Bilateral hippocampus, inclusive of all subfields, showed decreased activation across repetition of non-overlapping associations, consistent with a signature of associative novelty per se. In contrast, a left hippocampal region, peak in subiculum, showed increased activation across repetition of overlapping events relative to non-overlapping events, consistent with an associative mismatch response. These results reveal distinct forms of associative novelty detection within the hippocampus, and further suggest that a hippocampally-mediated associative mismatch response enables integration of related memories to support the flexible use of experience.

Dopaminergic Modulation of Resting State Networks in Parkinson’s disease

K Poston¹, W Shirer¹, F Tayim¹, V Menon², M Greicius¹
Departments of ¹Neurology and Neurological Sciences, ²Psychiatry and Behavioral Sciences, Stanford University, CA

Introduction: Resting state fMRI studies can be used to explore the functional connectivity of complex organized resting state networks (RSNs). Multiple canonical RSNs have been described corresponding to critical brain functions; however, modulation of these RSNs with dopamine replacement in PD has not been studied. In the present study we identified changes in striato-cortical network connectivity in Parkinson’s disease (PD) OFF and ON medications using resting state fMRI.

Methods: We acquired resting state fMRI data on 9 participants: 5 early PD (MDS-UPDRS-III 26.4±10.5) and 4 age-matched controls. PD patients were scanned both OFF and ON medications (PD-OFF and PD-ON). We applied independent component analysis (ICA) to the fMRI timeseries and used a template matching algorithm to identify the Motor Network (MN), Basal Ganglia Network (BGN), and a control network (Auditory Network (AN)). We conducted paired-sample t-tests and two-sample t-tests for each network to identify significant connectivity differences in PD-ON versus PD-OFF and PD versus controls, respectively. We confirmed these ICA findings with region-of-interest (ROI) analyses.

Results: For the ICA of the MN, controls and PD-ON had increased connectivity within the motor cortex compared to PD-OFF. In the BGN, PD-ON

FC paired-samples t-tests. A paired-samples t-test revealed greater connectivity within PD-ON than PD-OFF between the L-NAc and the Dorsal Anterior Cingulate Cortex, the right Nucleus Accumbens, the right Putamen, and the right Globus Pallidus.

had increased connectivity in the putamen and caudate compared to both PD-OFF and controls. We then selected the following ROIs for analysis: MN-right motor cortex, BGN-right caudate/putamen, and AU-right primary auditory cortex. MN connectivity was reduced in PD-OFF compared to controls (p=0.019). Connectivity increased in PD-ON compared to PD-OFF (p=0.006), and there was no difference between PD-ON and controls (p=0.446). BGN connectivity was also increased in PD-ON compared to PD-OFF (p=0.03). By contrast, no comparisons for ICA or ROI analyses in the control network (AN) reached significance.

Conclusions: PD-OFF showed reduced connectivity in RSNs associated with motor function with strengthened connectivity when patients were ON medication. These findings suggest RSNs could serve as objective biomarkers of PD motor function.

Decoding Subject-Driven Cognitive States with Whole-Brain Connectivity Patterns

W Shirer¹, S Ryali², E Rykhlevskaia², V Menon², MD Greicius¹
Departments of ¹Neurology and Neurological Sciences, ²Psychiatry and Behavioral Sciences, Stanford University, CA

Decoding specific cognitive states from brain activity constitutes a major goal of neuroscience. Previous studies of brain-state classification have focused largely on decoding brief discrete events and have required the timing of these events to be known. To date, methods for decoding more continuous and purely subject-driven cognitive states have not been available. Here, we demonstrate that free-streaming subject-driven cognitive states can be decoded using a novel whole-brain functional connectivity analysis. Ninety functional regions of interest (ROIs) were defined across 14 large-scale resting-state brain networks to generate a 3960 cell matrix reflecting whole-brain connectivity. We trained a classifier to identify specific patterns of whole-brain connectivity as subjects rested quietly, remembered the events of their day, subtracted numbers, or (silently) sang lyrics. In a leave-one-out cross-validation, the classifier identified these 4 cognitive states with 84% accuracy. More critically, the classifier achieved 85% accuracy when identifying these states in a second independent cohort of subjects. Classification accuracy remained high with imaging runs as short as 30--60 s. At all temporal intervals assessed, the 90 functionally defined ROIs outperformed a set of 112 commonly used structural ROIs in classifying cognitive states. This approach should enable decoding a myriad of subject-driven cognitive states from brief imaging data samples.

Functional parcellation of the brain into 90 regions of interest that cover the majority of cortical and subcortical gray matter. Group ICA applied to the resting-state data of 15 subjects yielded 14 ICNs of which 5 are shown in A (for all 14 ICNs, see Supplementary Fig. S2). Each ICN is thresholded to generate between 2 and 12 ROIs per ICN. When all 90 ROIs across the 14 ICNs are overlaid on a single brain image (B) the majority of cortical and subcortical gray matter is covered.

Digital Map of Emboli From Carotid Procedures

AC Rosen^{1,2}, J Stephens^{1,2}, AR Laird³, SB Eickhoff⁴, PM Fox³, G Chan¹, D Dinisshak⁵, M Ortega¹, B Lane^{1,6}, W Zhou¹
¹Palo Alto Veterans Affairs Health Care System, Palo Alto, CA; Departments of ²Psychiatry, ⁶Radiology, ⁷Surgery, Stanford University, CA; ³Research Imaging Institute, University of Texas Health Science Center at San Antonio, TX; ⁴Department of Psychiatry and Psychotherapy, RWTH Aachen University, Aachen, Germany; ⁵Pacific Graduate School of Psychology, Redwood City, CA

Background— Although carotid revascularization has a low rate of neurologic complications, subclinical microembolization visualized on postoperative diffusion weighted imaging MRI (DWI) is common. This study provides normative volumetric data on emboli to serve as a metric for lesion severity. We also characterize the regions vulnerable to procedure-associated emboli through a novel application of anatomic likelihood analysis (ALE).

Methods— DWI from 129 patients following carotid interventions were examined and embolic lesions were defined manually. Descriptive, image based analyses were performed characterizing the variability of lesion size, number, and location. Images were normalized and submitted to ALE.

Results— .. Forty five patients displayed post-procedure emboli. The frequency was higher for CAS (56.14% than CEA (18.06%), but the total volume of the lesions did not differ. Normative results were provided on lesion numbers, volume, and total lesion volume for a given patient. Patients with postoperative neurological symptoms were rare (8) but more common in those with a total lesion volumes greater than the 75th percentile (1128 mL). The areas with a high degree of convergence across embolic lesions included the anterior and posterior cingulate, white matter deep to the sensorimotor strip, parietal, and middle frontal gyrus, insula, basal ganglia, and temporoparietal junction.

Conclusions— Regions vulnerable to emboli include those implicated in memory (posterior cingulate), executive control and motor planning/speeded responses (anterior cingulate, middle frontal gyrus, basal ganglia), functions commonly affected in Alzheimer’s and vascular dementias. The overall distribution is consistent with what is traditionally termed the “border zone”. By identifying neural systems vulnerable to disruption, this study forms a basis for selecting a targeted neuropsychological battery for postoperative assessment.

The posterior cingulate (BA 31: coordinates 24, -24, 38) most likely to be affected by emboli is displayed in red.

Molecular imaging is the art of looking inside of a living organism or cell to evaluate biological processes, observe normal cell behavior, identify aberrant behaviors, and develop interventions to halt or rectify such abnormalities. Through molecular and functional imaging we have made huge strides in bridging many other disciplines such as, biology, chemistry, physics, and computer science and ultimately changing and improving how we use imaging in medicine.

An 18F-FBEM labeled Affibody for PET imaging of tumor EGFR expression

Z Miao, G Ren, H Liu, S Qi, S Wu, Z Cheng
Departments of Radiology, MIPS, BioX Program, Stanford University, CA

Objectives: Previously, a ^{64}Cu labeled anti-epidermal growth factor receptor (EGFR) Affibody (DOTA-ZEGFR:1907) was found to show excellent in vivo stability and good tumor-to-normal organ imaging contrast in xenograft mice model. The objective of this study was to further prepare and evaluate a radiofluorinated ZEGFR:1907 (termed as 18F-FBEM-ZEGFR:1907) for positron emission tomography (PET) imaging of tumor EGFR expression in living subjects.

Methods: The radiofluorination was accomplished through site-specific conjugation of the Ac-Cys-ZEGFR:1907 with N-2-(4-18F-fluorobenzamido)ethyl]maleimide (18F-FBEM). Binding affinity assay and in vivo biodistribution study was conducted with EGFR over-expression A431 cells and A431 xenograft tumor model. Correlation study of in vivo 18F-FBEM-ZEGFR:1907 PET imaging and in vitro Western blot analysis was then conducted in various EGFR over-expression tumors.

Representative microPET images (bottom) of nude mice bearing A431 tumor injected with 18F-FBEM-ZEGFR:1907 or 18F-FDG at 0.5 and 2 h post-injection. Arrow indicates the location of tumor.

Results: The resulting probe, 18F-FBEM-ZEGFR:1907, showed moderate specific activity (ca 10 GBq/ μmol) and low nanomolar affinity ($\text{KD} = 37\text{nM}$) to A431 cancer cells. Biodistribution studies in A431 xenograft model demonstrated that 18F-FBEM-ZEGFR:1907 displayed high tumor uptake at 3 h post injection (p.i.), and co-injection of a large excess of the unlabeled Ac-Cys-ZEGFR:1907 as a blocking agent significantly reduced tumor uptake (3.9 vs. 1.0 %ID/g, at 3 h p.i., 75% inhibition, $P < 0.05$). In vivo microPET imaging showed that 18F-FBEM-ZEGFR:1907 rapidly accumulated in the tumor and quickly cleared from the normal organs except liver and kidney, allowing excellent tumor-to-normal tissue contrast to be obtained. It was found that the tumor uptakes at 3 h p.i. quantified by 18F-FBEM-ZEGFR:1907 PET were in good correlation with the EGFR expression levels measured by Western assay ($P = 0.007$, $r = 0.60$).

Conclusions: 18F-FBEM-ZEGFR:1907 is a promising PET probe for imaging EGFR positive tumors and EGFR expression level

In vivo PET imaging to track mesenchymal stem cells labeled with ^{64}Cu -PTSM

K Chen, Z Miao, Z Cheng
Departments of Radiology, MIPS, BioX Program, Stanford University, CA

Objectives: With advancement of application of mesenchymal stem cells (MSCs) in biomedicine, in vivo tracking of MSCs in noninvasive, sensitive, quantitative, tomographic, and cell-non-hazardous ways is highly desired. Our study is to explore the advantages and disadvantages of tracking MSCs by uPET imaging using ex vivo ^{64}Cu - pyruvaldehyde-bis (N4-methylthiosemicarbazone) (PTSM) cell labeling.

Methods: Murine bone marrow derived-MSCs were isolated and labeled with ^{64}Cu -PTSM. In vivo uPET imaging was conducted after injection of MSCs into Bab/c mice. Biodistribution of labeled MSCs at early and late time point were measured. Also, cell uptake and efflux assay were conducted. Finally, the impact of ^{64}Cu -PTSM labeling on MSCs growth, differentiation were evaluated by cell counting and staining.

Results: ^{64}Cu -PTSM labeling efficiency of MSCs was around 75%. La-

(A) ^{64}Cu -PTSM labeling of MSCs for in vivo trafficking. (B) Representative microPET images of scid mice injected with ^{64}Cu -PTSM labeled MSCs (left) or ^{64}Cu -PTSM (right) at 1 and 4 h post-injection. The rectangle highlights the lung region.

beling has no impact on MSCs viability. In vivo uPET imaging of ^{64}Cu -PTSM labeled MSCs demonstrated quick lung accumulation at early time point (4 h) after tail vein injection of MSCs and showed decreased lung signal with time. Cell uptake of ^{64}Cu -PTSM by MSCs already reached plateau as early as 1 h (94.3%). Cell retention of ^{64}Cu -PTSM decreased over time and the value were 94.4% and 18.7% at 0.5 and 24 hr, respectively. Biodistribution result showed that lung uptake of ^{64}Cu -PTSM was 70.7% at 4 h, which indicated that MSCs could be quantitatively assessed at early time point by uPET imaging based on uptake and efflux assay results, however, late time point uPET imaging cannot reflect real distribution of labeled MSCs due to quick efflux of ^{64}Cu -PTSM. In addition, radiation of ^{64}Cu -PTSM had no significant impact on MSCs growth and differentiation measured by cell counting and staining.

Conclusions: This study demonstrates the feasibility of tracking MSCs by uPET imaging using ex vivo ^{64}Cu -PTSM cell labeling

^{64}Cu -Labeled Fibronectin Domain for PET Imaging of EGFR+ Tumors

BJ Hackel, R Kimura, SS Gambhir
Department of Radiology, Stanford University, CA

The fibronectin domain (Fn) is a beta-sandwich protein that has been utilized as a scaffold for engineering molecular recognition domains but has yet to be demonstrated for use in molecular imaging. A 98-amino acid Fn, engineered with picomolar affinity for epidermal growth factor receptor (EGFR), is site-specifically conjugated to 1,4,7,10-tetraazadodecane- $\text{N},\text{N}',\text{N}'',\text{N}'''$ -tetraacetic acid and labeled with ^{64}Cu with modest specific activity (36 mCi/mg). The ^{64}Cu -Fn tracer exhibits EGFR-specific binding to A431 epidermoid carcinoma cells in culture. The tracer is stable as it exhibits an unchanged HPLC chromatogram after 24h in 50% mouse serum at 37°. The ^{64}Cu -Fn ($\sim 50 \mu\text{Ci}$ injected via tail-vein) was used for positron emission tomography of EGFR-overexpressing A431 xenografts ($\sim 5\text{-}10 \text{ mm}$ diameter)

(A) Schematic of labeled protein. The fibronectin domain (depicted as the NMR solution structure of wild-type fibronectin domain (PDB code: 1TTG)) was engineered (mutated residues in green) for binding to EGFR. DOTA was conjugated to the sole primary amine (the N-terminus) and used to chelate ^{64}Cu . (B) PET imaging. A431 epidermoid carcinoma cells were xenografted into nude mice. ^{64}Cu -Fn3 (EGFR binder D' or non-binding control WT") was injected via the tail vein. 5 min. static scans were acquired at 1h post-injection.

in mice ($n=5$). The tracer exhibits good tumor localization ($2.6 \pm 0.8 \text{ \%ID/g}$ at 1h), retention ($2.1 \pm 0.5 \text{ \%ID/g}$ at 24h), and specificity ($5.1 \pm 1.2 \text{ tumor:muscle}$ at 2h). Specific targeting is statistically significant as verified by low localization to a tumor with low EGFR expression ($0.7 \pm 0.1 \text{ \%ID/g}$, $P < 0.005$); specificity is further demonstrated as a non-binding wild-type control fibronectin has low localization to the EGFR-overexpressing A431 xenograft ($0.7 \pm 0.1 \text{ \%ID/g}$ at 1h, $P < 0.005$). These results are corroborated by ex vivo gamma counting analysis of dissected tissues. These data represent the first reported use of the fibronectin domain for in vivo imaging and demonstrate the

potential for this domain to serve as a robust scaffold for the development of other molecular imaging agents.

Molecular Imaging

An 18F-labeled Agouti-related protein for PET imaging of integrin positive tumor

H Jiang^{1,2}, S Moore³, S Liu¹, H Liu¹, Z Miao¹, F Cochran³, J Cochran³, H Zhang², Z Cheng¹
¹Departments of Radiology, MIPS, BioX Program, ³Bioengineering, Stanford University, CA; ²Nuclear Medicine, Zhejiang University, Hangzhou, China

Objectives: A novel protein scaffold, agouti-related protein (AgRP) has been used to engineer mutants that bound to αvβ3 integrin with high affinity and specificity. In this study, for further clinical translation and applications, an 18F-labeled AgRP mutant(7C)was prepared and evaluated as a tumor imaging agent in vitro and in vivo.

Methods: AgRP-7C was synthesized by solid phase peptide synthesis. It was site-specifically conjugated with 4-nitrophenyl 2-18/19F-fluoropropionate to produce fluorinated peptide, 18/19F-FP-AgRP-7C.Competition binding assay of AgRP-7C and 19F-FP-AgRP-7C was performed using human glioblastoma U87MG cells that overexpress αvβ3 integrin.The biodistribution,metabolic stability and micro-positron emission tomography(PET)imaging studies of 18F-FP-AgRP-7C were conducted on U87MG tumor-bearing mice.

Results: Both AgRP-7C and 19F-FP-AgRP-7C specifically competed with 125I-echistatin for binding to U87MG cells. They showed high binding affinities (half maximal inhibitory concentration values were 9.40 and 8.37 nM,respectively).In

vivo micro-PET imaging demonstrated that 18F-FP-AgRP-7C accumulated rapidly in tumors (3.24 percentage injected dose per gram at 0.5 h post injection).It was quickly cleared from blood, resulting excellent tumor-to-normal tissue contrast.The bio-distribution study further demonstrated its high tumor uptake and rapid clearance. Furthermore,coinjection with a large molar excess of blocking peptide c(RGDyK) into U87MG tumor-bearing mice proved the integrin-binding specificity of 18F-FP-AgRP-7C in biodistribution and micro PET imaging studies. Serum stability and in vivo metabolite assays revealed that 18F-FP-AgRP-7C are sufficiently stable and suitable for in vivo molecular imaging.

Conclusions: 18F-FP-AgRP-7C exhibits promising in vivo properties such as rapid tumor targeting and good tumor-to-normal tissue ratios.AgRP is an excellent scaffold for protein engineering and could

be used to develop other targeting peptides for tumor imaging

Imaging Painful Neuropathic Nerves Using A Novel Sigma-1 Receptor (S1R) Radioligand With PET-MRI.

D Behera, B Shen, S Biswal, FT Chin
Department of Radiology, Stanford University, CA

Purpose: Sigma-1 receptors (S1R) modulate NMDA receptors and Ca2+-dependent processes, and therefore play a significant role in pain sensitization. S1R is upregulated in the nervous system in chronic pain and can potentially be used to highlight areas of increased nociceptive activity. We used 18F-FTC-146, a marker for S1R, and PET-MRI to detect increased S1R density in an injured nerve of a neuropathic pain model.

Materials and Methods: 18F-FTC-146 was synthesized via aliphatic nucleophilic fluorination using an automated module. Animal experiments were approved by Stanford IACUC. Adult male Sprague-Dawley rats were divided into 3 experimental groups (n=3): 1) Left Spared-Nerve Injury (SNI), a sciatic neuropathic pain model, 2) Sham surgery without nerve injury, and 3) control group without any surgery. The rats were allowed 4 weeks to heal and develop pain. Presence of pain in SNI was ascertained by testing for allodynia using von-Frey’s filaments. Each rat was given approximately 500 μCi of 18F-FTC-146 IV followed by an immediate dynamic scan of the thighs for 20 minutes using a microPET, followed by T1-weighted FSE images obtained using a 7T microMRI.

For blocking studies, Haloperidol (16 mg/kg IV) was given 20 min before tracer injection. PET and MRI images were fused (Amide image analysis software), and ROIs were placed on 5 mm segments of sciatic nerves, proximal to the level of injury in both hindlimbs of each rat using MR images. Signal was recorded from the fused PET images and normalized to background.

Results: Presence of allodynia only in the operated limb of SNI rats was confirmed (p<0.03). Higher 18F-FTC-146 signal was seen in the operated left sciatic nerve in the SNI group but not in the Sham or control groups (12.3, 5.2, 7.6 respectively). This difference disappears when blocked with haloperidol, demonstrating that the increased uptake in the sciatic nerve is due to specific binding with S1R.

Conclusion: Rats with neuropathic pain show increased 18F-FTC-146 uptake in the affected nerve. PET-MRI can be effectively used to study 18F-FTC-146 uptake in peripheral nerves.

Clinical Relevance: Combining the high sensitivity of PET with the excellent tissue contrast of MRI to locate nerve, 18F-FTC-146 PET-MRI can quantify neural S1R density and potentially identify chronic pain generators.

A novel probe with dual targeting mechanisms for tumor imaging using positron emission tomography

S Liu, H Liu, Z Miao, Z Cheng
Departments of Radiology, MIPS, BioX Program, Stanford University, CA

Objectives: Lipophilic cations, such as tetraphenylphosphonium analogs have been explored for tumor targeting because of their high accumulation in tumor cells which possess elevated mitochondria membrane potential than normal cells. Cyclic arginine-glycine-aspartic acid (RGD) peptides have also been extensively used for cancer imaging based on their intergin receptors targeting ability. In this study, we designed, synthesized and radiofluorinated a novel ligand (TPP-RGD) which contains both RGD and cationic phenylphosphonium moieties for tumor targeting through dual mechanisms. It is expected that the resulting probe could be advantageous such as high and specific tumor uptake ability due to its dual-targeting mechanisms.

Methods: The TPP-RGD heterodimer was synthesized by conjugation of triphenylphosphonium (TPP) and RGD through a lysine linker, then it was site specifically labeled with 18F via the p-nitrophenyl 2-18F-fluoropropionate (18F-NFP) prosthetic group. The receptor-binding affinity of 19F-FP-TPP-RGD was evaluated in vitro by competition

binding assay with 125I-echistatin using human glioblastoma U87MG cells. In vivo tumor-targeting efficacy of 18F-FP-TPP-RGD was evaluated by biodistribution and microPET studies.

Results: The receptor-binding affinities of RGD and 19F-FP-TPP-RGD were determined. 19F-FP-TPP-RGD displayed higher integrin αvβ3-binding affinity than RGD. In the microPET imaging study using U87MG-tumor bearing mice, 18F-FP-TPP-RGD had significantly higher tumor uptake compared with 18F-FP-RGD at all time points examined. The U87MG tumor uptake of 18F-FP-TPP-RGD was partially inhibited in the presence of an excess amount of unlabeled RGD.

Conclusions: Dual targets recognition of cell membrane receptor and mitochondria membrane potential showed significantly improved tumor-targeting efficacy. The same principle for designing other heterodimeric ligands could be applied to other receptor systems and imaging modalities in future studies

Novel 18F-labeled aliphatic probe for melanoma imaging

S Liu, H Liu, Z Miao, H Jiang, Z Cheng
Departments of Radiology, MIPS, BioX Program, Stanford University, CA

Objectives: Radiofluorinated benzamide and nicotinamide analogs have been demonstrated to be promising probes for melanoma PET imaging. The aim of this study was to explore the feasibility of using aliphatic compounds for development of new generation melanoma PET probes.

Methods: An aliphatic N,N-diethylethylenediamine precursor was directly labeled with a radiofluorination synthon, p-nitrophenyl 18F-fluoropropionate (18F-NFP), to produce a probe18F-FPDA. MicroPET imaging using 18F-FPDA was performed in melanoma murine models. The specificity of 18F-FPDA to melanoma was evaluated in vivo by biodistribution studies and micro-positron emission tomography (microPET) imaging in C57BL/6 mice bearing B16F10 murine melanoma tumors.

Results: Starting with precursor 18F-NFP, the total reaction time for 18F-FPDA, including final high-performance liquid chromatography purification, is about 30

min, with decay-corrected radiochemical yield of 79.8%. The B16F10 cell study demonstrated by significant different uptake in tyrosine-treated and untreated B16F10 cells in vitro. In pigmented-enriched B16F10 xenografts, tumor uptakes reached 5.41 %ID/g at 0.5 h post injection and the sustained tumor uptake at 2 h post injection was 3.05 %ID/g, while in the non-pigmented U87MG and PC3 models, the tumor uptakes were only the background levels. Due to the high selectivity between targeted and non-targeted organs for 18F-FPDA, the animal PET imaging study yielded a high tumor-to-muscle ratio of approximately 8:1 at 1 h and 14:1 at 2 h post injection.

Conclusions: The new tracer 18F-FPDA was synthesized with high yield via 18F-NFP and the tracer exhibited high B16F10 tumor-targeting efficacy, and favorable in vivo pharmacokinetics. Further testing and clinical translation of 18F-FPDA for noninvasive clinical evaluation of suspected malignant melanoma are warranted

Development of 18F-labeled picolinamide probes for melanoma PET imaging

S Liu, H Liu, Z Miao, Z Cheng
Departments of Radiology, MIPS, BioX Program, Stanford University, CA

Objectives: The aim of this study was to synthesize and evaluate the 18F-picolinamide probes (18F-P3BZA and 18F-P4BZA) for the imaging of malignant melanoma.

Methods: 18F-fluoropicolinamides were prepared by radiofluorination reactions using no-carrier-added 18F-fluoride and evaluated in vivo by biodistribution studies and micro-positron emission tomography (microPET) imaging in C57BL/6 mice bearing B16F10 murine melanoma tumors.

Results: 18F-fluorination of the corresponding bromopicolinamide precursors was achieved in yields of 10-20% (decay corrected on the basis of 18F-fluoride). The total synthesis time was less than 1 hour. The radiochemical purity of the 18F-labeled probes was more than 98% and the specific activity was 100-150 GBq/μmol. Noninvasive microPET and direct tissue sampling experiments demonstrated that the probes had melanin-specific tumor targeting in subcutaneous B16F10 melanoma xenografts,

Schematic structure of the probes 18F-P3 and 18F-P4 (left) and representative microPET images (right) of nude mice bearing melanoma B16F10 injected with the probe at 0.5, 1 and 2 h post-injection. Arrow indicates the location of tumor.

18F-fluoropicolinamides could be promising imaging agents for the detection of melanoma

which yielded a tumor-to-blood ratio of approximately 20:1 at 1 h and greater than 30:1 at 2 h. Quantitative microPET imaging studies showed that 18F-P3BZA had tumor uptake of 11.8 ± 2.2, 13.2 ± 2.4, and 14.6 ± 3.2 %ID/g at 0.5h, 1 h, and 2 h postinjection, respectively. Of note, the 18F-P3BZA demonstrated good in vivo stability as evidenced by the low bone uptake in biodistribution studies.

Conclusions: The new 18F-picolinamide probes were synthesized with high specific activity via one-step 18F-fluorination within a short time frame. The probes exhibited high tumor uptake and metabolic stability, as well as favorable in vivo pharmacokinetics. These findings suggest that

Development of [18F]AIF-NOTA-RGD2 probe for microPET imaging in U87MG-tumor bearing mice

S Liu, H Liu, H Jiang, Z Cheng
Departments of Radiology, MIPS, BioX Program, Stanford University, CA

Objectives: Clinical translation of 18F-labeled arginine-glycine-aspartate (RGD) peptides is partially hindered by the multi-step and laborious radiosynthesis. The goal of this study was to investigate the feasibility of one-step 18F-labeling of a dimeric RGD peptide for microPET imaging via a simple chelation reaction between Al18F and NOTA-RGD2.

Methods: Cyclic peptide E[c(RGDyK)]2 (RGD2) was conjugated with macrocyclic chelator 1,4,7-triazacyclononane-1,4,7-triacetic acid (NOTA) and labeled with Al18F to synthesize [18F]AIF-NOTA-RGD2. The peptide conjugate's affinity and specificity to integrin were assessed by cell-based receptor binding assay, and the tumor targeting efficacy of [18F]

Radiosynthesis of [18F]AIF-NOTA-RGD2 and a representative microPET image of nude mice bearing U87MG injected with the probe at 0.5 h post-injection. Arrow indicates the location of tumor.

AIF-NOTA-RGD2 was evaluated in a subcutaneous U87MG glioblastoma xenograft mouse model.

Results: The NOTA-RGD2 conjugate could be radiofluorinated in good yield within 40 min via Al18F intermediate. The IC50 of [19F]AIF-NOTA-RGD2 determined by U87MG cell-based receptor binding assay was 46 ± 4.4 nM using 125I-echistatin as radioligand. Quantitative microPET imaging studies using [18F]AIF-NOTA-RGD2 demonstrated the high tumor uptake, fast clearance from body, and good tumor to normal organ ratios.

Conclusions: The NOTA-RGD2 conjugate has been successfully labeled with Al18F in one single step. The good in vivo behavior plus the short synthesis route for [18F]AIF-NOTA-RGD2 warrant further exploration for kit-like production of 18F-labeled RGD PET radiopharmaceutical for integrin αvβ3 imaging and potential clinical translation

Profiling EGFR in triple negative breast tumors using PET

G Ren, Y Xu, Z Miao, S Qi, H Liu, Z Cheng
Departments of Radiology, MIPS, BioX Program, Stanford University, CA

Objectives: Triple Negative Breast Cancer (TNBC) represents a group of refractory breast cancer with aggressive clinical manifestations as well as poor prognosis. Epidermal growth factor receptor (EGFR) expression is strongly associated with TNBC progression and it may serve as a therapeutic target for TNBC. We aimed to use EGFR Affibody based PET imaging to profile EGFR expression and to evaluate the response from anti-EGFR treatment in TNBC tumor bearing mice.

Methods: Ac-Cys-ZEGFR:1907 was chemically synthesized using a solid phase peptide synthesizer and then site-specifically conjugated with 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) for radiolabeling or N-2-(4-18F-fluorobenzamido)-ethyl]-maleimide (18F-FBEM). The in vitro cell uptake study was performed using TNBC SUM159 cells. The biodistribution and microPET imaging using 64Cu-DOTA-ZEGFR:1907 or 18F-FBEM-ZEGFR:1907 were evaluated in nude mice bearing subcutaneous SUM159 tumors.

Decay corrected coronal microPET images of a nu/nu mouse bearing TNBC MDA-MB-231 (top) or SUM159 (bottom) after tail vein injection of 64Cu-DOTA-ZEGFR:1907

Results: Ac-Cys-ZEGFR:1907 was successfully synthesized and radiolabeled with 64Cu. Biodistribution study showed that tumor uptake value of 64Cu-Ac-Cys-ZEGFR:1907 remained at 4.07 ± 0.93 %ID/g at 24 h in nude mice (n = 4) bearing SUM159 xenografts. Furthermore, microPET imaging study demonstrated that 64Cu-DOTA-Ac-Cys-ZEGFR:1907 and 18F-FBEM-ZEGFR:1907 could both specifically delineate the EGFR positive TNBC tumor in vivo (Figure).

Conclusions: The study successfully demonstrated that 64Cu-DOTA-Ac-Cys-ZEGFR:1907 and 18F-FBEM-ZEGFR:1907 are promising molecular probes for PET imaging of EGFR expression in TNBC. The anti-EGFR targeted therapy is currently undergoing in TNBC models and EGFR targeted imaging will be utilized for profiling the EGFR as an effective TNBC biomarker

Characterization of 177Lu-Affibody-HSA for cancer radionuclide therapy

G Ren, Y Xu, Z Miao, S Qi, H Liu, Z Cheng
Departments of Radiology, MIPS, BioX Program, Stanford University, CA

Objectives: The epidermal growth factor receptor (EGFR) is an attractive target for radionuclide therapy of disseminated head and neck carcinomas. EGFR specific Affibodies have shown excellent tumor localizations in PET and SPECT studies, but on the other hand, display extremely high kidney uptakes (>100%ID/g). This represents a critical concern for high doses to the radiation sensitive kidneys. We have recently demonstrated that a human serum albumin (HSA)-HER2 Affibody conjugate exhibits improved pharmacokinetics. The purpose of this study is to further explore whether radiolabeled EGFR-HSA bioconjugates could be suitable for radionuclide therapy of EGFR expressing tumors.

Methods: HSA was modified by a site-specific conjugation with DOTA-NHS and the bifunctional crosslinker Sulfo-SMCC. The EGFR Affibody analog Ac-Cys-ZEGFR:1907 was then covalently conjugated with the HSA through the sulfo-SMCC, and the resulting bioconjugate DOTA-HSA-ZEGFR:1907 was further radiolabeled with 64Cu and 177Lu. Radiometal labeled

DOTA-HSA-ZEGFR:1907 was subjected to in vitro cell uptake and internalization studies using the human oral squamous carcinoma cell line SAS (n=5). PET, SPECT and biodistribution studies were examined using SAS tumor-bearing mice (n=4).

Results: Radiolabeling with 64Cu as well as with 177Lu resulted in high radiochemical yields (>70%). The in vitro stability of 177Lu-DOTA-HSA-ZEGFR:1907 in mouse serum was >80% at 168 h. Cell uptake studies displayed a significant (8.4% at 4 h) and specific uptake and the internalization of 177Lu-DOTA-HSA-ZEGFR:1907 could be verified. PET and SPECT using 64Cu-DOTA-HSA-ZEGFR:1907 and 177Lu-DOTA-HSA-ZEGFR:1907, respectively showed good tumor imaging contrasts. The imaging results were consistent with the biodistribution data: 177Lu-DOTA-HSA-ZEGFR:1907 displayed good tumor uptakes (5.1% ID/g) and high liver uptakes (31.5% ID/g) and relatively low

kidney uptakes (8.5% ID/g) at 72 h p.i.

Conclusions: 177Lu-DOTA-HSA-ZEGFR:1907 is a promising agent for radionuclide therapy of EGFR expressing head and neck carcinomas

Signal Conditioning Technique for Position Sensitive Photodetectors

FWY Lau^{1,2,3}, P Reynolds^{1,2,3}, A Vandenbroucke^{2,3}, H Ho¹, CS Levin^{1,2,3}
Departments of ¹Electrical Engineering, ²Radiology, ³MIPS, Stanford University, CA

When position sensitive photodetectors such as Position Sensitive Avalanche Photodiodes (PSAPDs) are used to read out pixelated scintillation crystal arrays, the flood histogram exhibits a non-linear, pin-cushion shape. This is due to the non-linear charge sharing occurring in the resistive sheet on the position sensitive detector. We present an electronic readout technique that allows the shape of the flood histogram and crystal identification capability to be manipulated while scaling the signal dynamic range to fit the dynamic range of the electronics. The technique involves adding a resistor on

Silicon Photomultiplier-based Detector Array for TOF-PET

JY Yeom¹, V Spandoudaki¹, CS Levin^{1,2,3}
Departments of ¹Radiology, MIPS, ²Physics, ³Electrical Engineering, Stanford University, CA

Time-of-Flight (ToF) information in Positron Emission Tomography (PET) can contribute to a significant improvement in the reconstructed image signal to noise ratio, enabling image contrast improvement, a reduction in patient radiation dose, and/or shorter scan times

In this study, we propose a multi-element LSO-SiPM (Silicon photomultiplier) detector architecture, that reads out each element individually to maximize the time resolution performance. Two 4x4 SiPM detector modules were fabricated by tiling individual 3 mm SiPM elements (Hamamatsu MPPC). Each 4x4 SiPM array is readout with two edge-on preamplifier boards, each hosting 8 wideband 3 GHz bandwidth RF amplifiers (see figure). The temperature of each detector module is regulated by a Peltier cooler and all 32 SiPMs are individually biased through a 32-channel bias supply board. To assess the performance of these

modules, single 3 x 3 x 5 mm³ and 3 x 3 x 20 mm³ LSO crystals were coupled to individual SiPMs of each detector module. The detectors were operated in coincidence and their signals were read out by a high speed oscilloscope. Measurements were performed in terms of linearity, energy and coincidence time resolution by irradiating the coincidence detectors with a 511 keV photon emitting Ge-68 source placed in-between.

A coincidence timing resolution of 240 +/- 2.3 ps (FWHM) was obtained at 71.5 V for the 5 mm length crystals and 350 +/- 3.1 ps (FWHM) at 71.7 V was achieved for the 20 mm length crystals.

These results verify that individual element readout for LSO-SiPM based detectors provides good timing performance for TOF-PET systems.

Algorithms for Multi-Interaction Photon Events in Sub-Millimeter CZT PET Detectors

G Chinn^{1,2}, CS Levin^{1,2,3,4,5}
Departments of ¹Radiology, ²MIPS, ³Bioengineering, ⁴Electrical Engineering, ⁵Physics, Stanford University, CA

We are investigating a new cadmium zinc telluride (CZT) detector module with 0.5 mm³ reconstructed spatial resolution for small animal PET and plant imaging. Inter-pixel scatter will occur in 75% of the detected events either degrading the spatial resolution or reducing the sensitivity if the events are discarded. CZT also has poor time resolution leading to reduced contrast because of a higher random coincidence rate. We will use the kinematics of Compton scattering to accurately position inter-pixel scatter events, so that these events can be used in the image reconstruction without degrading the spatial resolution. Further, we can estimate the incident photon direction from Compton kinematics to reject random coincidence photons. The performance of these Comp-

ton kinematic based algorithms are dependent on the geometric configuration of the detector. Therefore, we are investigating a new split-layer design and comparing it against a conventional detector geometry. We examined the contrast and contrast-to-noise ratio (CNR) of the reconstructed images and show up to a 64% improvement in contrast and 48% improvement in CNR over conventional energy weighted mean positioning and a time window for randoms rejection.

Single Ended Readout of Depth-of-Interaction in Scintillation Crystals for High Resolution PET

F Taghibakhsh¹, CS Levin^{1,2}
Departments of ¹Radiology, MIPS ²Electrical Engineering, Stanford University, CA

Incorporating photon depth-of-interaction (DOI) in PET image reconstruction improves image resolution, especially for high resolution applications such as organ specific or small animal imaging. We are investigating the performance of our novel DOI PET detector based on pulse height modulation with single-ended readout of scintillation crystals. The goal is to develop a less complex, cost-effective DOI detector technology. In the design under study, one end of each crystal element has a light absorbing coating to provide scintillation light absorption that varies with DOI; the other end has a sensor to measure the scintillation light. We experimented with a 4x4 array of 1x1x20 mm³ LYSO crystal elements, optically coupled to a position sensitive solid state photomultiplier (PS-SSPM). We observed that the DOI resolution varies from ~ 4.0 mm to ~ 8.0 mm (FWHM) along the crystals. The global energy and time resolution were measured to be 16.2% and 8ns (FWHM), respectively. Simulations of a PET system comprising 304 of

these DOI detectors arranged on a 100 mm diameter detector ring were performed. We compared reconstructed images with and without DOI information based on the proposed single-ended light readout method. Results indicate that the proposed DOI detector improved spatial resolution such that, in contrast to non-DOI detectors, the single-ended readout DOI detector successfully resolved 20 μCi hot spheres of 2 mm diameter, placed 4 mm apart at 30 mm distance from the center of the FOV in the transversal direction. Compared to non-DOI and 2-layer DOI detectors, the proposed DOI detector achieved 110% and 31% better contrast resolution, respectively. The single-ended readout DOI detector based on pulse height modulation is compatible with standard PET detector configurations with photodetectors on only one end of the crystal array, and provides a cost effective DOI solution for high resolution PET applications.

Point Spread Function for PET Detectors Based on a Probability Density Function

E González^{1,2}, J-Y Cui⁴, G Pratz², PD Olcott^{2,3}, M Bieniosek⁴, CS Levin^{1,2,3,4,5}

¹Stanford Molecular Imaging Scholars (SMIS) program, Departments of ²Radiology, ³BioEngineering, ⁴Electrical Engineering, ⁵Physics, Stanford University

We propose a new approach to calculate the Point Spread Function (PSF) for PET detectors based on the probability density function (PDF) of the line segment connecting two detector elements. Positron Emission Tomography (PET) events comprise the detection and positioning of pairs of oppositely directed 511 keV photons. The most significant blurring effect in PET is the considerable size of the detector elements, which causes uncertainty in the detected position of photons. Typically this physical blurring is modeled in the forward direction, following photons from the source to the detectors. This work presents an analytical framework for calculating this physical blurring, from the inverse approach, that is from the detector to the source. The kernel is derived from the parametrization of the line segment whose endpoints are random variables described by the intrinsic

detector response function distribution. This kernel is calculated in a first order approximation, and when compared against a measured PSF profile yields less than 8% root mean square (RMS) differences. Also, from this kernel a PSF-FWHM function of the distance to the center of the scanner is derived. The ratio between the PSF-FWHM and the intrinsic detector resolution (FWHM0) agrees with the Monte Carlo simulations. For detectors whose intrinsic response functions are described by Gaussian profiles we calculated ratios 1/√2 and √5/8 at the center (R=0) and halfway from the center at (R=system-radius/2) respectively in agreement with published values of 1/√2 and 0.85; similarly for uniform (rectangular) profiles we get 1/2 and 3/4 which are equal to published values.

Performance of an Electro-Optical-Coupled PET Detector for Time-of-Flight PET/MRI

MF Bieniosek^{1,2}, PD Olcott^{2,3}, CS Levin^{1,2,3}

Departments of ¹Electrical Engineering, ²Radiology, MIPS, ³Bioengineering, Stanford University, CA

Combining PET with MRI in a single system provides clinicians with complementary anatomical and molecular information. However, current combined PET/MRI systems do not have time-of-flight (ToF)-PET capabilities due to certain design choices. We have developed an MRI-compatible front-end electronic system with fast timing capabilities for ToF-PET. Our approach employs a fast arrival time pickoff comparator to digitize the timing information and a laser diode to drive a fiber-optic cable to optically transmit timing information. The comparator and electro-optical link show 17ps +/- 0.2ps fwhm jitter in response to a fast digital pulse. When coupled with 3mmx3mmx5mm LYSO scintillation crystals and Hamamatsu MPPC silicon photomultipliers (SiPM), the comparator and electro-optical link achieved 283ps +/- 6.8ps fwhm coincidence time resolution using a Na-22 positron source, while maintaining detector energy resolutions of 15.0% +/- 1.7%, and 13.5% +/- 1.4% fwhm at 511keV

A New Data Path Design for PET Data Acquisition System: A Packet Based Approach

E Kim^{1,2}, PD Olcott^{1,3}, CS Levin^{1,2,3,4}

¹Departments of Radiology, MIPS, ²Electrical Engineering, ³Bioengineering, ⁴Physics, Stanford University, CA

We are proposing a new data path design for Position Emission Tomography (PET) Data Acquisition (DAQ) systems. The proposed design can transmit, receive, and process all PET data through a single data stream. Instead of using separate paths for data, clock and control signals individually, which is the general case for conventional DAQ systems, the proposed system uses a packet concept to identify and process the various data types in a single fast data stream. The proposed design increases flexibility during the design phase and enables efficient debugging, which is essential for scaling up channels in a DAQ system. New packets can easily be defined without changing the hardware. Debugging a specific board or a channel in a large system can be done efficiently by sending a packet to that board or channel requesting information.

We defined four different packet types to differentiate information in the data stream: singles packet, coincidence packet, configuration packet, and status packet. The length and overhead of these packets are optimized to increase overall throughput. We implemented the algorithm in a Xilinx FPGA board and partitioned the logic in a modular structure. The system consists of a high-speed network interface, a daisy-chain interface, an ADC interface, an ADC processor, a coincidence processor, an FSL interface, and an Ethernet interface. The coincidence processor can process single events up to 150M events/s and the ADC processor can receive new events locally up to 100M event/s. Coincidence events are sent to an image reconstruction PC with a throughput of more than 1M event/s.

Methods to enhance the sensitivity of simultaneous imaging of multiple PET isotopes

E González^{1,2}, PD Olcott^{2,3}, M Bieniosek⁴, CS Levin^{1,2,3,4,5}

¹Stanford Molecular Imaging Scholars (SMIS) program, Departments of ²Radiology, ³BioEngineering, ⁴Electrical Engineering, ⁵Physics, Stanford University, CA

Multi-isotope PET (MIP) can distinguish the biodistributions of two simultaneously injected PET tracers, where one tracer has an isotope that is a pure positron emitter that generates two-photon coincidences, and the other emits a positron and a gamma ray in cascade yielding a triple coincidence. However triple coincidence detection suffers from very low sensitivity. This work presents a method to significantly enhance the sensitivity of triple coincidences for multi-isotope PET by adding an extra detector dedicated for the detection of the third prompt gamma in coincidence with the annihilation photons. We performed Monte Carlo simulations with Zr-89 and F-18 isotopes, and measurements with Na-22 and Ge-68. F-18 and Ge-68 are pure positron emitters; on the other hand, Zr-89 and Na-22 emit 909 keV and 1275 keV prompt gamma rays, respectively. For the simulations, a phantom was acquired in a simulated Siemens microPET R4 system with 8 cm diameter, 5 cm thick detector slab of BGO placed at one end of the system to increase detection efficiency of the third gamma ray. The simulations indicate a 3-fold increase in sensitivity with the extra detector added. For the measurements, we arranged

two LYSO crystals coupled to Hamamatsu MMPC silicon photomultipliers (SiPM) for the detection of 511 keV photons in coincidences and one large 8cm diameter, 2cm thick detector slab of LYSO coupled to a PMT dedicated for the detection of the 1275 keV gamma ray. The measured ratio of the triple-coincidence counts divided by the double-coincidence detection counts is 0.037±0.003, which compares well with the analytically calculated ratio of 0.042 estimated from intrinsic and geometric efficiency considerations. Furthermore, the 511 keV scintillation detectors were mounted on a linear stage that translated the detectors while acquiring double and triple coincidences counts simultaneously in order to generate one-dimensional profiles of the Na-22 and Ge-68 point sources. The triple-coincidence allows the distinction of the Na-22 point source profile from the standard 511 keV double-coincidence profile of the Ge 68 source.

Characterization of RF-transparent electro-optically coupled PET/MRI block detectors

PD Olcott^{1,3}, G Glover², CS Levin¹
Department of Radiology, ¹MIPS, ²RSL, ³Bioengineering, Stanford University, CA

Objectives: We wish to make a MR compatible PET block detector that has little mutual effect between a PET and MRI system. The PET detector should use multiplexing to reduce the number of readout channels; finally, the MRI should be able to use a split transmit receive for MRI acquisition.

Methods: We fabricated two block detectors consisting of a 6 x 6 array of 2.1 mm x 2.1 mm x 20 mm LYSO crystals coupled to a 4 x 4 array of SiPM devices. The block detectors were Faraday shielded and powered using a battery. We characterized the coincidence flood histogram, energy resolution, and timing resolution for the block detectors in a 1.5T MRI. We designed the RF system to be able to transmit through the PET detector. We characterized the two detectors with and without RF body transmitter using split transmit and receive only coil for the MRI acquisition. We used a 3D gradient recalled echo (GRE) sequence to test for image artifacts, and a high duty cycle spin-echo pulse train to test for RF blanking and interference from the PET detector.

Results: We resolved all crystals in the 6x6

Characterization of a RF transparent PET/MRI compatible block detector that uses electro-optical coupling to couple the scintillation signals from a PET detector over multi-mode optical fibers. The PET detectors did not introduce and PET/MRI artifacts and had excellent energy, spatial, and timing resolution.

array with a 3.1:1 peak-sigma separation. We achieve a global delay corrected coincidence time resolution 2.55 +/- 0.051 ns FWHM and a per crystal gain corrected energy resolution of 15.5 +/- 0.7% FWHM @511 keV. There were no differences in spatial, energy or timing resolution when operating in the 1.5T field. The PET detectors did not saturate during RF transmit, and can be operated simultaneously with the RF transmitter. No MRI image artifacts were seen when transmitting using the RF body coils and receiving using a receive only 8-channel receive coil.

Conclusions: We have demonstrated a working PET/MRI block detector that is RF transparent, and has little mutual influence between MRI and PET.

All-optical encoding of PET detector signals

A Grant¹, P Olcott¹, CS Levin^{1,2}
Departments of ¹Bioengineering, ²Radiology, Stanford University, CA

Typical PET scanners use many electronic readout channels and dedicated electronic coincidence processing boards that contribute significantly to system complexity and costs. We have developed a method of optically encoding the position, energy, and arrival time of annihilation photon interactions in PET detectors with fast (150 ps FWHM) coherent optical pulse trains from telecommunications-grade lasers, and are developing a method of multiplexing all of the detector outputs in a PET scanner to a single optical fiber system output channel. This will allow the elimination of much of the currently used processing electronics, achieving coincidence time resolutions of <300 ps FWHM while decreasing system cost and complexity. We constructed a single channel proof-of-concept system using fast 10 Gbps off-the-shelf optical components and a silicon photomultiplier (SiPM) coupled to an LSO:Ce crystal. A custom PCB based on a fast comparator with adjustable threshold and hysteresis creates fast electronic pulses from the detector outputs. These electronic pulses are converted to optical pulses, and detector interaction information is encoded into precise delays between the pulses. Using this system, we demonstrated the encoding of photon position, energy, and arrival time into four coherent optical pulses. We measured extremely low timing jitter for the optical pulses (3 ps) and collected preliminary 22Na energy spectra (energy resolution 24.9% FWHM at 511 keV – not optimized yet) with all-optical pulse encoding. Optical encoding and multiplexing could greatly facilitate the construction of high resolution time-of-flight PET scanners with thousands of detector channels.

(a) Four-pulse train with characteristic channel identifying time $\Delta t = 5$ ns and ToT (time over threshold) of ~ 25 ns (x scale 5 ns/div). Each detector channel has a unique Δt value, allowing channel identification during data readout. Δt is created by splitting each optical channel into two arms, delaying one arm with a fiber loop, then recombining the two arms. Single event shown; ToT varies with pulse energy. The position of the first positive pulse gives the photon arrival time. (b) Energy spectrum (blue) of 22Na point source with LSO:Ce/SiPM, by measuring ToT from optically-encoded pulses. 511 keV peak visible in center. Green persistence plot shows the range of recorded ToT values between positive and negative pulses (x scale 10 ns/div). Energy resolution is 24.9% FWHM at 511 keV in preliminary (not optimized) system trials.

Studies of Electrode Design for a Sub-mm Resolution 3-D Position Sensitive CZT PET Detector

Y Gu, CS Levin
Deptartments of Electrical Engineering and Radiology, MIPS, Stanford University, CA

A 40×40×5 mm³ monolithic cadmium zinc telluride (CZT) crystal photon detector is being developed for a high-resolution small animal PET system with an 8×8×8 cm³ field-of-view (FOV). The detector employs a novel cross-strip electrode pattern capable of detecting the 3-D position of individual photon interactions to enable uniform 1 mm spatial resolution throughout the FOV as well as other advanced performance features. Through a series of 6 studies the CZT photon detector's charge collection efficiency and the spatial, time and energy resolution were experimentally determined as a function of the electrode pattern dimensions. This work presents generally applicable insights for all strip-electrode CZT photon detectors, and specifically the electrode dimensions and biasing details that optimize important PET performance parameters of the detector under development.

The detector studied employs a cross-strip electrode pattern with 100 μm wide anode strips on a 1 mm pitch, interspersed with steering

Subplots (a) to (d) show, respectively, (a) 3-D high-resolution small animal PET system with a 8x8x8cm³ field-of-view using CZT detectors, (b) anode face of the 40x40x5 mm³ cross-strip CZT detector, (c) collimated slit-beam experiment for characterizing the detector cathode response, and (d) photon detection efficiency (event count) of 5 mm wide cathodes as a function of collimated slit beam position.

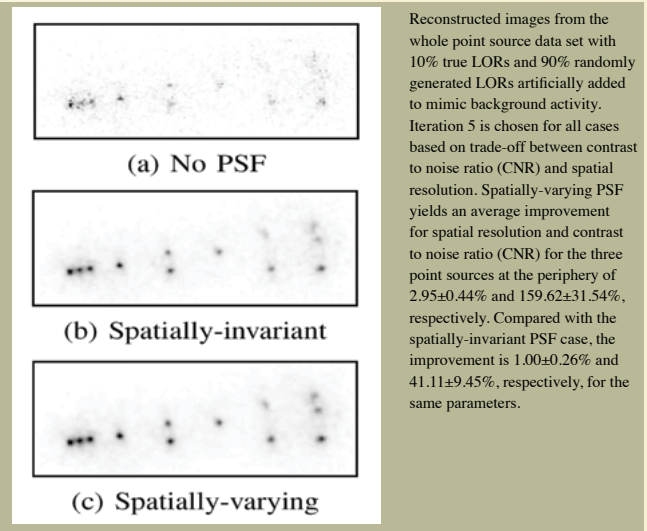

electrodes of varying width that enhance anode charge collection. Cathode strips are oriented orthogonal to the anodes, with width and pitch of 3 mm or 5 mm. Because of the requirement of photon interaction positioning at sub-pitch resolution, 3 mm wide cathode strips were favored due to their finer structure. However, the higher charge sensitivity of 5 mm wide strips offered higher photon detection efficiency, and higher spatial resolution uniformity in the direction orthogonal to the electrode planes. 5 mm wide cathodes also offered a higher uniformity in coincidence time resolution (51.68 ± 19.53 ns), which varies with the photon interaction position. The detector charge collection efficiency is independent of the steering electrode width, but sensitive to the applied steering electrode bias. Complete charge collection occurred at -100 V relative to the anodes. Finally, for photon interactions depositing charge on two adjacent anode strips, steering electrodes of 400 μm width yielded the best photopeak energy resolution at 511 keV of $4.92 \pm 0.31\%$ FWHM.

Data-Driven Spatially-Varying Point Spread Function for List-Mode PET Reconstruction on GPU

J Cui¹, G Pratz², S Prevhal⁵, B Zhang⁵, L Shao⁵, CS Levin^{1,3,4}
Departments of ¹Electrical Engineering, ²Radiation Oncology, ³Radiology, ⁴MIPS, Stanford University, CA; ⁵Philips Healthcare, CA

We present a novel method to accurately model the spatially-varying point spread function (PSF) of a PET system reformulated for list-mode reconstruction on a graphics processing unit (GPU). The spatially-varying PSF for each LOR is modeled as an asymmetric Gaussian function whose variance changes asymmetrically according to the orientation of the line of response (LOR) and the voxel geometry. To fit the PSF parameters, a point source is imaged at twelve locations in a Philips Gemini TF PET system. To avoid tedious mechanical calibrations, the accurate point source location is estimated directly from the list-mode data. We introduce the “canonical sinogram” to enable reading out the sampled PSF directly from a stack of sinograms by exploring the rotational symmetry of the system matrix. The critical parameters for the PSF model are obtained by solving a convex optimization problem based on the measured point source data. The spatially-varying PSF is efficiently incorporated into the image reconstruction process on the GPU using the CUDA texture memory. The reconstruction algorithm incorporating the measurement-based shift-varying PSF

Reconstructed images from the whole point source data set with 10% true LORs and 90% randomly generated LORs artificially added to mimic background activity. Iteration 5 is chosen for all cases based on trade-off between contrast to noise ratio (CNR) and spatial resolution. Spatially-varying PSF yields an average improvement for spatial resolution and contrast to noise ratio (CNR) for the three point sources at the periphery of $2.95 \pm 0.44\%$ and $159.62 \pm 31.54\%$, respectively. Compared with the spatially-invariant PSF case, the improvement is $1.00 \pm 0.26\%$ and $41.11 \pm 9.45\%$, respectively, for the same parameters.

takes 103 milliseconds per iteration to process a million LORs in a 75x75x26 image on a GeForce GTX 480 GPU, which is 190 times faster than a non-PSF implementation on a state-of-the-art central processing unit (CPU), and only 6.8% slower than a spatially-invariant fixed-width Gaussian kernel on the same GPU. Compared with reconstruction without PSF modeling, this shift-varying PSF reconstruction shows an average improvement of spatial resolution and contrast-to-noise ratio for point sources at the periphery of the field-of-view of $2.95 \pm 0.44\%$ and $159.62 \pm 31.54\%$, respectively. Compared with reconstruction with a spatially-invariant PSF, the average improvements are $1.00 \pm 0.26\%$ and $41.11 \pm 9.45\%$, respectively. These results indicate that the fast and accurate spatially-varying PSF reconstruction promises better resolution and contrast recovery with very small additional computational cost.

Evaluation of photon depth-of-interaction compensation for time-of-flight PET

V Spanoudaki¹, J-Y Cui², J-Y Yeom¹, CS Levin^{1,2,3}

Departments of ¹Radiology, MIPS ²Electrical Engineering, ³Physics, Stanford University, CA

Time-of-flight (ToF) PET is a technique that reduces the positioning uncertainty of the emission point of 511 keV photons during PET data collection. The uncertainty is defined mathematically by a “kernel” or distribution of position along a system response line. Since photons are positioned more accurately along the system response lines, ToF information enhances the PET image signal-to-noise ratio (SNR), facilitating lesion detection and reduction of patient dose. 511 keV photons interact over a range of depths in the PET photon detectors (depth-of-interaction, DoI). We are currently developing a dual-head DoI-ToF prototype for experimental evaluation of the effects of DoI on ToF-PET performance. Two different DoI identification schemes, based on single-ended readout of one or multiple crystal layers, are under evaluation. We found from simulations and measurements that DoI information enables more accurate positioning of the ToF kernel and more precise estimation of the ToF

Top: Experimental setup to determine the dependence of time resolution on DoI for a 3x3x20 mm3 scintillation crystal. A 2x2x3 mm3 LSO crystal is used for electronic collimation of 511 keV photons emitted from the positron emitter (22Na). Bottom: Experimentally derived dependence of the coincidence time resolution FWHM (ToF kernel width) and the centroid of the coincidence time difference distribution (ToF kernel position) as a function of DoI along the 20 mm length scintillation crystal.

kernel width. Experiments show the dependence of photon arrival time information on DoI. For variations in photon DoI over a 20 mm length scintillation crystal with rough surfaces, we experimentally observed a 15% degradation of the time resolution (ToF kernel width) and a 100% shift in the mean time difference (centroid of the ToF kernel) between coincident 511 keV photons along a given response line. These results were used to parameterize the ToF kernel information from every list-mode event using a second order polynomial of the DoI for each involved detector element. The effect on image quality is assessed by Monte Carlo simulations of a water phantom containing hot and cold spheres placed in a warm background with a 6:1 activity concentration ratio. We found that 2 iterations of the iterative image reconstruction algorithm optimizes the reconstructed image SNR for the various sphere sizes with and without DoI compensation.

Study of Readout for Groups of PSAPDs Used in a 1 mm3 Resolution

PD Reynolds^{1,2}, A Vandenbroucke², F Lau^{1,2}, CS Levin^{1,2}

Departments of ¹Electrical Engineering, ²Radiology, MIPS, ³Bioengineering, Stanford University, CA

We are developing a 1 mm3 resolution, high sensitivity PET system for breast cancer imaging. The system comprises two 16cm x 9cm x 2cm detector panels, each containing 2304 position sensitive avalanche photodiodes (PSAPDs) coupled to 8x8 arrays of 1mmx 1mm x 1mm LYSO scintillation crystal elements, for a total of 294,912 crystal elements. The LYSO-PSAPD detectors are multiplexed in pairs (“dual LYSO-PSAPD modules”) to reduce the number of channels, resulting in 9216 channels per panel. The readout system has a modular data acquisition structure based on a 36-channel readout ASIC. This system design has multiple dual LYSO-PSAPD modules read out by a single ASIC, with each dual module having an adjustable high voltage bias and gain. This paper characterizes performance when small groups of dual LYSO-PSAPD modules are read out simultaneously.

Top, log scale flood histograms demonstrate good individual crystal separation. Bottom, PSAPD energy spectra show the 511 keV peak and x-ray escape.

The multiple detector readout was tested with 3 dual modules connected to a single ASIC. The detectors are placed side by side, in a 3 x 2 array of position sensitive scintillation detectors. A Na-22 point source was used to generate 511 keV photons and irradiate the modules from a few centimeters above. List-mode single photon data was collected.

A similar setup was used to test the coincidence timing. Two independent data acquisition units were each used to read out 3 dual modules. A Na-22 point source was placed between two of the dual LYSO-PSAPD detectors to generate coincident 511 keV photons. The coincidence time difference was energy gated to be in the 511 keV peak and was corrected for per crystal position time delay and signal amplitude variations.

Data collected from 6 PSAPD detectors showed average global energy resolutions of 9.42±0.38% FWHM at 511 keV and a paired photon time resolution of 7.23±0.21 ns (4.74±0.02 ns unpaired) FWHM at 511 keV.

References/Funding Source Submitted for presentation at the 2011 IEEE Medical Imaging Conference, Valencia, Spain. NIH R01CA119056, R01CA119056-S1 (ARRA), R33 EB003283, and R01CA120474.

Measuring 3D 511 keV Photon Interaction Locations in Position Sensitive Detectors

A Vandenbroucke¹, FWY Lau², PD Reynolds², CS Levin^{1,2,3,4}

Departments of ¹Radiology, MIPS, ²Electrical Engineering, ³Bioengineering, ⁴Physics, Stanford University, CA

Our objective is to construct high resolution PET cameras for breast and small animal imaging using a unique scintillation detector design that directly measures depth-of-interaction (DOI).

Our design employs detector modules comprising two 8x8 arrays of 1x1x1 mm3 LYSO crystals coupled to one Position Sensitive Avalanche Photo-diode (PSAPD) each, mounted on a common flexible circuit. Four of these modules were stacked together in a dedicated structure to form a 3-D positioning detector. Signals were routed over flexible cables to a discrete board housing signal conditioning electronics. The discrete board was connected to another board featuring a readout ASIC, ADCs and an FPGA. Data was collected using a 22-Na point source. The common signal of each PSAPD served as a trigger. When any module received a signal above a certain threshold, all 4 modules were read out.

Upper left shows a mechanical drawing of a detector module. Upper right shows a photograph of a detector module with various components indicated in the photo. Bottom shows a photograph of the setup used for measuring 511 keV interaction locations in 3 dimensions.

Flood histograms show that all 64 crystal elements in each array are identified, with a global energy resolution of 18.1 +/- 0.1%. When limiting the data set to only contain hits with an energy falling within the photo-peak range in one particular module, and an open energy window in the other modules, we observed less than 2.5% hits in those other modules, indicating low electronic cross-talk and the ability to distinguish photo-electric interactions in different layers, thus enabling 3-D localization.

We also investigated multiple interaction events by considering events for which interactions occurred in multiple layers, with an energy deposition between 30 and 450 keV in each individual layer and a total deposited energy between 410 and 610 keV. We studied the occurrence of such events in different module layer combinations.

In conclusion, this paper presents the first experimental data from a scintillation detector capable of determining the position of individual interactions in 3-D. The design shows low electronic cross-talk between layers and low noise per readout channel.

Quantification of Inflammation in Inflammatory Bowel Disease by Molecular Ultrasound Imaging

N Deshpande¹, Y Ren¹, K Foygel¹, M Schneider³, PJ Pasricha², JK Willmann¹

Departments of ¹Radiology, ²Gastroenterology, ³Hepatology, Stanford University, CA; ³Bracco Diagnostics

Inflammatory bowel disease (IBD) is a chronic relapsing and remitting inflammatory condition of the gastrointestinal tract that needs regular and accurate monitoring. The goal of our study was to assess the potential of molecular ultrasound (US) imaging using microbubbles (MB) targeted to the inflammation marker P-selectin (MBP-selectin) to quantify inflammation and to predict remission of inflammation following treatment in a chemically-induced colitis mouse model. Binding affinity and specificity of MBP-selectin was tested in a flow chamber under flow shear stress conditions (at 100 sec-1). In vivo binding specificity of MBP-selectin to P-selectin was tested in 10 mice with colitis (induced by rectal administration of TNBS) and in 10 control mice without colitis using non-linear in vivo US imaging (25 MHz). Furthermore, in vivo molecular US imaging signal in treated (n=6; prednisolone therapy) versus non-treated (n=6; saline only) mice was compared over 3 subsequent treatment days. Attachment of MBP-selectin was significantly (p=0.01) higher to P-selectin positive (stimulated by TNF-alpha) than unstimulated endothelial cells and compared to MBControl (p=0.003). Furthermore, attachment of MBP-selectin significantly (R2 >0.8, p=.01) correlated with expression levels of P-selectin on endothelial

cells as quantified by flow cytometry. In vivo US signal of colitis was significantly higher (p=0.0003) with MBP-selectin compared with MBControl (Figure), and significantly (p=0.01) dropped by 53% following injection of blocking antibodies. In treated animals, in vivo US imaging signal significantly (p=.03) decreased during the course of treatment while in non-treated mice US signal in the colon wall remained elevated. In vivo US imaging signal significantly (R2 >0.6; p=.04) correlated with P-selectin expression levels as assessed by ex vivo assays (WB and IF). In conclusion, molecular US using MBP-selectin allows non-invasive in vivo quantification and monitoring of inflammation at the molecular level in a chemically-induced colitis mouse model. This study lays the foundation for an eventual future clinical translation of molecular US imaging for monitoring inflammation in IBD.

Figure. (A) Transverse B-mode image of the colon wall (white arrows) in a mouse with TNBS-induced colitis using a high-resolution US scanner. Molecular ultrasound imaging signal in colon wall (arrows) following injection of MBP-selectin (B) was significantly higher compared to control conditions following injection of MBControl (C), suggesting binding specificity of MBP-selectin to P-selectin in inflamed colon wall.

Longitudinal Assessment of Expression Levels of Tumor Angiogenic Markers with Molecular Ultrasound Imaging

N Deshpande, Y Ren, K Foygel, J Rosenberg, JK Willmann
Department of Radiology, Stanford University, CA

The purpose of this study was to evaluate molecular ultrasound (US) to non-invasively assess the temporal expression levels of three angiogenic markers, $\alpha v\beta 3$ integrin, endoglin, and VEGFR2 on tumor vascular endothelial cells in vivo. Three types of targeted microbubbles (MBIntegrin, MBEndoglin, MBVEGFR2) were designed and the binding specificity of MB to their respective targets was tested on endothelial cells (positive and negative for angiogenic marker expression) under flow shear stress conditions (at 100 sec-1) in a flow chamber. In vivo molecular US imaging using the three different MB was performed at three different tumor stages (small, medium, large size) of three different subcutaneous tumor xenografts (breast, ovarian, pancreatic cancer) in mice (n=48) and was correlated with angiogenic marker expression levels as assessed by western blotting. Attachment of all three targeted MB was significantly (p=0.003) higher to positive than to negative cells and the attachment was significantly (p=0.026) decreased by blocking antibodies. The number of attached targeted MB significantly (R2>0.8, p=.0001) correlated with the expression levels of

Transverse contrast-enhanced ultrasound images of a subcutaneous breast cancer tumor graft (arrows) in a nude mouse, imaged longitudinally at small (A), medium (B), and large (C) tumor sizes following intravenous administration of MBEndoglin. Endoglin expression (shown as green overlay on B-mode images) was highest at small tumor size and decreased at medium and large tumor sizes.

the angiogenic markers on cell lines as assessed by flow cytometry. For breast and ovarian cancer, endoglin expression was significantly higher than $\alpha v\beta 3$ integrin (p=0.005) and VEGFR2 (p=0.0003) expression in small and medium tumors as assessed by in vivo US imaging. In contrast, in pancreatic cancer, $\alpha v\beta 3$ integrin was highest in small tumors compared to endoglin and VEGFR2 (p=0.05) and endoglin expression peaked in medium and large tumors. In all tumors types, expression levels of all markers were lowest (p=0.005) in large tumors (Figure). In vivo US imaging signal significantly (R2>0.6; p<.05) correlated with ex vivo western blotting results for all three markers. In conclusion, molecular US imaging allows non-invasive assessment of the expression levels of different tumor angiogenic markers that vary during tumor growth in various subcutaneous human tumor xenografts. The results provide insights into tumor angiogenesis biology and may help in defining imaging targets for both early cancer detection and treatment monitoring using molecular US imaging.

tion levels of all markers were lowest (p=0.005) in large tumors (Figure). In conclusion, molecular US imaging allows non-invasive assessment of the expression levels of different tumor angiogenic markers that vary during tumor growth in various subcutaneous human tumor xenografts. The results provide insights into tumor angiogenesis biology and may help in defining imaging targets for both early cancer detection and treatment monitoring using molecular US imaging.

A Novel Motion Correction Technique for Contrast-enhanced Ultrasound Imaging of Tumor Vascularity

MA Pysz¹, I Guracar², K Foygel¹, JK Willmann¹

¹Department of Radiology, MIPS, Stanford University, CA; ²Siemens Medical Solutions, Mountain View, CA.

The purpose of our study was to develop and test a real-time adjustable motion correction algorithm for contrast-enhanced ultrasound (CEUS) imaging in human colon cancer xenografts in mice receiving vascular disruptive tumor treatment. A motion correction technique that measured horizontal and vertical B-mode pixel displacements using sum of absolute difference in a size- and location-adjustable tracking box, was incorporated into the software of a clinical US scanner (Sequoia Acuson 512, Siemens). Contrast-enhanced US imaging in the maximum intensity projection mode (14 MHz, MI=0.26) was performed on subcutaneous human colon cancer xenografts (implanted on backs of mice). Extent of tumor vascularity (expressed as % contrast area) was calculated in real-time with and without motion correction in tumors with different grades of vascularity (low, moderate, high; n=16), and in mice with (n=5) and without (n=5) treatment with a vascular disrupting agent (VDA). In moderately vascularized tumors, the

Subcutaneous human colon cancer xenograft imaged with contrast-enhanced ultrasound with (left) and without (right) novel real-time adjustable motion correction technique. Note substantial difference of measured tumor vascularity in mouse taking a spontaneous deep breath. A region of interest (yellow line) was placed to outline the tumor boundaries.

effect of motion correction on the measured tumor vascularity was significantly (P<.001) higher (mean differences, 13.3% \pm 2.3%) compared with tumors with low (mean differences, 3.2% \pm 2.7%) or high (mean differences, 4.8% \pm 2.5%) vascularity. The differences in tumor vascularity measurements with and without motion correction were also highest in animals taking a spontaneous deep breath when the tumors were moderately vascularized (mean differences, 25.4% \pm 5.2%; Figure) compared to low (mean differences, 13.4% \pm 7.2%) and highly (mean differences, 12.0% \pm 10.0%) vascularized tumors. Following VDA treatment, tumor vascularity significantly (P=.003) decreased on motion-corrected images (51.7% \pm 25.1% to 19.7% \pm 11.4%), whereas vascularity minimally increased (P=.03) in non-treated

mice (from 64.0% \pm 15.4% to 70.7% \pm 18.9%). In conclusion, the effects of real-time motion correction for CEUS imaging of tumor vascularity substantially depend on the grade of tumor vascularity and the extent of motion, and may improve CEUS imaging for treatment monitoring.

Cationic and Neutral Microbubble and DNA Dose Effects on Ultrasound-mediated Gene Delivery In Vivo

C Panje¹, MA Pysz¹, DS Wang¹, Y Ren¹, M Schneider², JK Willmann¹

¹Department of Radiology, MIPS, Stanford University, CA; ²Bracco Research, Geneva, Switzerland.

Ultrasound (US)-mediated sonoporation using contrast microbubbles (MB) is a promising strategy for therapeutic gene delivery. The purpose was to assess the influence of different MB and DNA doses on in vivo gene delivery to skeletal muscles in mice using novel cationic and neutral MB. Cationic and neutral MB were characterized for their charge and amount of bound plasmid DNA encoding Firefly luciferase (pFluc). Protective effects of cationic MB in binding DNA were tested by incubating pFluc-MB mixtures with DNase and assessing the extent of degraded DNA. US-mediated gene delivery of 4 μ g pFluc to endothelial cells with 5E7 cationic or neutral MB was performed and quantified using the luciferase assay kit. US-mediated in vivo gene delivery to hindlimb skeletal muscle was performed with varying cationic and neutral MB (1E7, 5E7, 1E8, or 5E8 with 50 μ g pFluc) or pFluc doses (10, 17.5, 25, 37.5, or 50 μ g with 1E8 MB). Bioluminescence imaging was performed every 24h post-transfection to compare each dose and to negative control conditions (no MB or US). pFluc binding of cationic MB was significantly (P<0.01) higher and more protective to DNase degradation than neutral MB. Fluc activity using cationic MB was significantly higher both in cell culture (P<0.01) and

YOYO-1-labeled pFluc (green) binds to cationic (A) but not to neutral (C) microbubbles (MB) as evidenced by confocal microscopy (B, D). In vivo bioluminescence imaging of ultrasound-mediated delivery of 50 μ g pFluc mixed with 1x108 MB demonstrates significantly higher imaging signal in skeletal muscles when using cationic versus neutral MB and compared to control conditions (no MB, no US). Differences between cationic and neutral MB was highest when the fraction of bound DNA was maximized.

fraction) resulted in only 1.3-fold higher gene delivery compared to neutral MB. US-mediated gene delivery is more efficient with cationic compared with neutral MBs when the fraction of bound DNA is maximized.

in vivo (P<0.006) experiments and was significantly lower in negative controls (P<0.002). The magnitude of in vivo gene delivery using cationic compared to neutral MB increased linearly (R2=0.9) with the amount of bound pFluc (P<0.05). Cationic MBs bound with 10 μ g pFluc (30% bound fraction) resulted in 3.4-fold higher gene delivery compared to neutral MB. In contrast, cationic MB mixed with 50 μ g pFluc (6% bound

A Novel Paradigm to Markedly Enhance the Specificity of Gene Expression in Hepatocellular Carcinoma Using MicroRNAs

JA Ronald^{1,2}, RH Katzenberg^{1,3}, CH Nielsen^{1,4}, HJ Jae^{1,3}, LV Hofmann^{1,3}, SS Gambhir^{1,2}

Department of ²Radiology, ¹MIPS, ³Interventional Radiology, Stanford University, CA; ⁴Cluster for Molecular Imaging & Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.

In vivo miRNA-regulated gene expression. Inclusion of miRTs for the liver-specific miR-122 into expression vector significant reduces (by approximately two log-orders) Fluc2 liver activity following hydrodynamic delivery in mice.

In cancer gene therapy potent, tumor-specific expression is of utmost importance to improve outcome and ensure safety. Tumor-specific promoters may be used but often promote weak tumor and “leaky” non-tumor expression. Hence, novel strategies for specific, yet robust, expression are needed. MicroRNAs (miRNAs) are short, endogenous RNAs that inhibit translation by binding to complementary sequences (miRTs) in target mRNAs. Here we explore the ability to achieve the coveted tumor-on/liver-off expression profile

in a rat hepatocellular carcinoma (HCC) model by engineering potent vectors regulated by miRNAs. The levels of 11 miRNAs downregulated in human HCC were compared in both rat HCC (n=5) and liver (n=8) by qRT-PCR. 7 miRNAs were reduced (p<0.05; range 3 to 16-fold) in rat HCC including, miR-26a, miR-101a, miR-122, miR-125a-5p, miR-125b, miR-139-5p and miR-150. The robustness of miRNA repression in vitro and in vivo was explored by constructing 3 vectors all expressing firefly luciferase (Fluc2) driven by the strong CMV promoter (pcDNA3.1) either with no miRTs (pCMV-Fluc2), or 4 tandem sense or 4 anti-sense miRTs (miRT and anti-miRT, respectively) for the liver-specific miR-122 inserted in the 3' untranslated region. HUH-7 (miR-122 +ve) cells were transfected and Fluc2 activity 24 hours later was decreased ~80% (p<0.05) for the miRT versus the 2 control vectors. Each vector was then hydrodynamically injected via the tail-vein of Balb/c mice (n=3 per group) to assess the degree of repression in liver. Importantly, average radiance (p/sec/cm2/sr) in bioluminescent images taken 48 hours post-injection was markedly reduced (~100-fold; p<0.05) with the miRT (4.7e6 \pm 5.2e5) versus the control vectors (pCMV-Fluc2=4.1e8 \pm 1.0e8; anti-miRT=3.2e8 \pm 1.8e8) (Figure). Based on these exciting results current work focuses on generating additional vectors regulated by one or more miRNAs and expressing a reporter gene fused to a therapeutic gene for testing in tumor-bearing rats. This is the first work to explore the use of miRNAs to control transgene expression in HCC and should have broad applicability for other cancers and imaging across cell lineages.

Imaging of Vascular Progression Within a Lymph Node in a Lymphoma Mouse Model

K Ito¹, BR Smith¹, N Parashurama¹, C Miething², S Lowe², SS Gambhir¹
¹Department of Radiology, MIPS, Stanford University, CA; ²Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, USA.

Non-Hodgkin’s Lymphoma is a heterogeneous disease with significant mortality. Data we have accumulated indicates that angiogenesis plays an important role in the genesis of lymphoma. We reasoned that intravital microscopy (IVM) could be used to assess the vascular progression of lymphoma in mouse models. We utilized a model of lymphoma in which tail vein-injected murine lymphoma cells undergo homing to the inguinal lymph node. Two types of murine lymphoma cell lines, p53^{-/-} (Doxorubicin (DOX) and Cyclophosphamide (CTX) resistant: IC50= 46.2nM and 84.1µM, respectively) and ARF^{-/-} (DOX and CTX sensitive: IC50= 3.5nM and 10.0µM, respectively) were used. We tail-vain injected 1×10⁶ cells of both groups and PBS as a control into C57BL/6 mice (p53^{-/-} and ARF^{-/-}: N=4, cont.: N=3). On the day of imaging, the inguinal lymph node was exposed by creating a tissue flap. IVM image stacks of blood vessels (using a near infrared intravascular dye) within the inguinal node were obtained and inguinal lymph node size was measured at days 0, 7, 14, and 21

Intravital Microscope (IVM) Images in the Inguinal Lymph Node of a Living Mouse. a) Control mouse. Day7 after injection of PBS. b) Day 7 after injection of p53^{-/-} lymphoma cells. Enhanced angiogenesis is significantly higher in panel b) as compared to panel a).

after injection and analyzed using Image J software. We furthermore developed a lymph node window chamber in order to serially image vascularization within the lymph node. We identified that micro vessel number and circulating dye intensity in the inguinal lymph node were significantly higher in p53^{-/-} cell-injected mice compared to ARF^{-/-} cells and control mice at day 7 (p<0.01). Mean vessel length was significantly longer in both p53^{-/-} cells and ARF^{-/-} cells-injected groups compared to control mice at day 7 (cont. vs. p53^{-/-} p<0.001, cont. vs. ARF^{-/-} p<0.05). At days 14 and 21, vessel growth was higher in both groups compared to control. There is no significant difference in inguinal lymph node size between p53^{-/-} cells and ARF^{-/-} cells-injected mice. These data indicate that inguinal lymph node imaging in an orthotopic murine lymphoma model using IVM is a powerful tool for elucidating unprecedented detail in lymphoma development.(KI and BS contributed equally.)

Affibody-Functionalized, Multimodal Raman/Fluorescence Nanoparticles for Biomarker Profiling and Tumor Imaging

JV Jokerst¹, Z Miao¹, C Zavaleta¹, CT Chan¹, Z Cheng^{1,2}, SS Gambhir^{1,2}
Departments of ¹Radiology, MIPS, ²Bioengineering, Bio-X, Stanford University, CA

Surface enhanced Raman spectroscopy (SERS) nanoparticles (NPs) offer picomolar sensitivity and extensive multiplexing in vivo. While these NPs’ photo-physical properties are established, their use as biological probes requires further efforts. Here we report targeted hybrid NPs with tunable, multiplexed SERS signal, NIR fluorescence for high throughput cell assays, and selective binding to the cancer markers epidermal growth factor receptor (EGFR) and αvβ3 integrin. The NPs contain a gold core/silica shell functionalized with affibodies—an intriguing ligand for molecular imaging purposes due to its small size, high affinity, and capacity to be rapidly reprogrammed to different biomarkers. These affibodies coat NPs via a hetero-bifunctional, PEG-based linker with controlled synthesis resulting in ~200 ligands per NP. The SERS NPs are optimized in cell culture via the fluorescence mode. For NP with EGFR-specific affibodies incubated with A431 cells, 6.3-fold greater signal was observed by flow cytometry versus isotype control NPs and 55-fold greater signal than non-targeted NPs. Blocking studies with free affibody (“cold

a) The NP has a gold core and silica clad, fluorescent label (red), passivated by PEG (green), and covalently coated with EGFR-specific affibody (purple). This probe labeled A431 tumors ex vivo; b) tumor is blocked with free affibody prior to staining, which decreases Raman signal; c) EGFR labeling by NPs as indicated by Raman signal; d) untargeted NPs produce low non-specific binding.

probe”), followed by the targeted NP, decreased signal by 7.3-fold. NP detection in vivo after sub-cutaneous injection yielded detection limits of 30 pM and 6 pM via fluorescence and Raman, respectively. Next, the bioconjugated NPs labeled EGFR on A431 tumors excised from Nu/Nu mice. The SERS signal via EGFR-targeted NPs was 11 times higher than unlabeled particles (n = 3; p< 0.05). Tumors blocked with unlabeled affibody produced signal 6 times lower (n = 3; p< 0.08). Alternatively, the αvβ3 integrins in U87MG cells were labeled via NPs with IgG antibody. Integrin signal (targeted NPs) to background (bare NPs) ratios of 25:1 and 13:1 were obtained for the particles via SERS and fluorescence, respectively. To the best of our knowledge, this is the first demonstration of affibody ligands deployed in tandem with multimodal SERS nanoparticles for biomarker identification. These results suggest that full utilization of SERS NPs will have significant potential for applications in living subjects.

Evaluation of a PET Antibody Tracer for Monitoring Lymphoma Therapy in a Humanized Transgenic Mouse Model

A Natarajan¹, G Gowrishankar¹, CH Nielsen^{1,3}, S Wang¹, N van Bruggen⁴, SS Gambhir^{1,2}
Departments of ¹MIPS, Radiology, ²Bioengineering, Bio-X, Stanford University, CA; ³Cluster for Molecular Imaging & Department of Clinical Physiology, Nuclear Medicine and PET, University of Copenhagen, Rigshospitalet, Denmark; ⁴Biomedical Imaging, Genentech, South San Francisco, CA

Positron emission tomography (PET) tracers offer a broad spectrum of clinical applications in oncology, including improved tumor diagnosis, staging, surveillance, monitoring of antitumor therapy, and tumor tissue characterization. Aim: To radiolabel and image in pre-clinical models an antibody based PET tracer, ⁶⁴Cu-DOTA-Rituximab (Rmab). Method: The ⁶⁴Cu was chelated to DOTA-NHS linked Rituximab. QA of the radiotracer was established by HPLC, sterility, and in vitro live cell uptake assay. To validate the study multiple radiolabeling and imaging experiments were carried out in three groups of mice; two groups of mice had huCD20 transgene (CD20TM) that expresses the human CD20 on their B cells. The study groups of mice are as follows; a) control (nude mice, n=2) received Rmab 200µCi/dose, b) negative (CD20TM, n=2): received 2mg/kg pre-dose of cold Rituximab prior to 2h of Rmab dose of 200µCi, and c) positive (CD20TM, n=2): Rmab alone 200µCi/

The small animal PET-CT transgenic mice images show after tracer injection of ⁶⁴Cu-DOTA-rituximab (200µCi/2µg) at 24h: Figure A) received rituximab pre-dose of 2mg/kg 2h prior to tracer injection; B) mouse received only tracer no pre-dose. Figure B shows the specific uptake of tracer in the spleen where huCD20 expressing B cells.

huCD20. Conclusion: We have optimized and validated Rmab radiochemistry and PET imaging in mice for clinical translation to applications in lymphoma patients.

Preliminary Intravital Microscopic Analysis Reveals Macrophage Uptake of Circulating Nanotubes and RGD-dependent Delivery into Tumor

BR Smith¹, H Rallapalli¹, J Prescher¹, C Zavaleta¹, J Rosenberg¹, Z Liu², H Dai², SS Gambhir¹
Departments of ¹Radiology, MIPS, ²Chemistry, Stanford University, CA

Molecular targeting of nanoparticles (nps) is known to increase tumor uptake, but is believed to do so via a direct np ligand-receptor binding mechanism. It is also well-known that macrophages (macs) tend to accumulate in tumor. The present work unexpectedly suggests that circulating macs can be programmed by molecularly-targeted nps to increase preferential deposition into tumor. We used intravital microscopy (IVM) to visualize U87MG tumor (EGFP) in a dorsal window chamber mouse model (n=25 mice) as we IV injected single-walled carbon nanotubes (SWNTs) conjugated to cy5.5 dye. In real time, we visualized uptake of SWNTs into circulating macrophages (identified via flow cytometry) and their behavior within tumor interstitium. We also used the intrinsic Raman signature of SWNTs to quantify overall tumor uptake. SWNTs were conjugated to RGD which binds integrin αvβ3 RAD peptide and unconjugated SWNTs (plain) were controls. We observed rapid uptake (< 1 min) of SWNTs into macs with plain SWNTs, compared with several hours for peptide-conjugated SWNT uptake. Macs observed in vasculature were categorized as 1) non-interacting (free-flowing) 2)interacting cells (crawling along the luminal surface). At one day p.i., we observed more non-interacting macs containing plain SWNTs than those with RAD, and more RAD than RGD (p=0.0001). However, interacting macs displayed the reverse trend (0.0057), suggesting that having peptides linked to SWNTs encouraged mac interaction with the endothelium. Last, across the first week p.i., we found more non-interacting macs in the plain condition than in the RGD-SWNT condition (p<0.0001), with no difference between RAD and plain SWNTs. We observed (1) SWNT-laden macs in tumor interstitium and (2) total SWNTs in tumor increased over the first week p.i. for RGD/RAD, but only for the first 3 days p.i. for Cy5.5. Together with the above results, the data imply SWNT delivery into tumor via the mac “Trojan Horse.” Our data thus indicate that RGD may encourage not only typical np ligand-receptor binding routes, but also indirect uptake into (and perhaps on the surface of) macrophages. These RGD-SWNT laden macrophages appear to be preferentially taken up into tumor compared with SWNTs without RGD. In conclusion, these results could (1) lead to improved np design to increase mac delivery, (2) transform non-specific tumor macs into specific delivery vehicles, and (3) may explain the high tumor uptake displayed by SWNTs.

Dual Wavelength Imaging of a Novel Activatable Photoacoustic Probe

J Levi¹, SR Kothapalli², TJ Ma³, B Khuri-Yakub³, SS Gambhir^{2,1}
Departments of ¹Radiology, Canary Center at Stanford; ²MIPS; ³Electrical Engineering, Stanford University, CA

Photoacoustic tomography has the capability of providing images of high spatial resolution and high contrast at depths up to 5 cm. As the breadth of application for this modality grows, so does the need for probes with high specificity. We report here the design, synthesis and evaluation of an activatable probe that shows great promise in providing highly specific photoacoustic images. Before the activation by its target, matrix metalloprotease MMP-2, the probe, an activatable cell penetrating peptide labeled with two different chromophores, shows photoacoustic signal of similar intensity at the two wavelengths corresponding to the absorption maxima of the chromophores. After the cleavage, the dye associated with the cell penetrating part of the probe accumulates in the cells, resulting in photoacoustic signal seen only at one of the wavelengths. The subtraction of the photoacoustic images at two wavelengths reveals the location of the cleaved probe only, as the signals at two wavelengths for the non-activated probe cancel out. To evaluate our approach towards smart photoacoustic probes, we have incubated human fibrosarcoma cells, HT 1080, with three probes: non-activated, MMP-2 specific probe, BHQ3-ACPP-Alexa750; non-activated, MMP-2 non-specific probe, BHQ3-CPP-Alexa750; and cleaved probe BHQ3-CPP. The uptake of the cleaved probe was clearly distinguished from the accumulation of both non-activated probes by subtracting the photoacoustic images taken at two wavelengths corresponding to the absorption maxima of the two chromophores used, BHQ3(675nm) and Alexa750(750nm) (Figure 1 d,e). A great utility of our probe in combination with dual wavelength imaging lies in the possibility of detection of the cleaved probe in the presence of the high levels of non-activated probe, a challenging task to attain in an absorbance-based modality. This method could prove useful in pre-clinical models, photoacoustic guided surgical interventions, treatment efficacy evaluations, as well as many other applications.

Photoacoustic imaging of the smart probe accumulation in cells. HT1080 cells were incubated with 150 μ L of 10 μ M solution of BHQ3-CPP-Alexa750, BHQ3-ACPP-Alexa750 or BHQ3-CPP for 10 minutes and embedded in triplicate in an agar phantom. (a) Fluorescence image (λ 675 nm, ICG emission filter) of the agar phantom shows location of the cells as well as the uptake of BHQ3-CPP-Alexa750 and BHQ3-ACPP-Alexa750. Photoacoustic images of the agar phantom with embedded cells taken at two wavelengths: 675 nm (b) and 750 nm (c). Subtraction of the images taken at 675 nm and 750 nm resulted in an image with distinct signal coming from the cells incubated with the cleaved probe, BHQ3-CPP (d). The accumulation of different probes in the cells was quantified from the subtraction image using mean photoacoustic values for each well (e). Errors bars represent the standard deviation of the mean of triplicates. Accumulation of BHQ3-CPP probe was significantly different ($p < 0.05$) from the accumulation of both BHQ3-ACPP-Alexa750 and BHQ3-CPP-Alexa750. Colors bars represent relative photoacoustic signal intensity.

Comparison of 18F-FDG and 18F-FLT small-animal PET imaging in an orthotopic glioblastoma mouse model

E Mittra¹, H Fan-Minogue¹, FI Lin¹, V Sriram², S Medicherla², SS Gambhir^{1,3}
Departments of ¹Radiology, Nuclear Medicine, ³Bioengineering, Stanford University, CA; ²Merck Research Laboratories, Palo Alto, CA

Objectives: Pre-clinical orthotopic models of glioblastoma are important for the development of novel therapies. Non-invasive methods to assess response to therapy that can also be used in the clinic are favored, but currently limited. We investigate the utility of 18F-FDG and 18F-FLT small-animal PET in an orthotopic glioblastoma model in mice, using bioluminescence (BLI) as a reference. **Methods:** Fifteen 9 week-old nude mice (7 FDG; 8 FLT) were injected with 3×10^5 U87 MG-Luc2 cells directly into the right subcortical region. BLI and FDG or FLT PET were performed on these mice weekly for 5 weeks using dedicated small animal imaging apparatus. Region of interest (2D) analysis was used to calculate the photon flux per area (p/s/cm²/sr) and mean percent injected dose per gram (%ID/g), respectively. The BLI and PET signals were compared to assess their relative utility. **Results:** There was a

PET is not suitable. Subsequent work will evaluate the ability of these models to assess response to therapy.

Use of Tumor Targeted Raman Nanoparticles for Early Detection of Colon Cancer in Conjunction with a Newly Developed Raman Endoscope

C Zavaleta¹, JV Jokerst¹, JT Liu², MJ Mandella², E Garai^{1,2}, J Hardy^{2,4}, C Contag^{1,2}, SS Gambhir^{1,3}
Departments of ¹Radiology, ²Pediatrics, ³Bioengineering, ⁴Microbiology and Immunology, Stanford University, CA

We have recently developed a new clinical imaging strategy utilizing a customized Raman endoscope in conjunction with locally administered tumor targeting Raman nanoparticles, to be applied during routine colonoscopy. This strategy could offer a new way to sensitively detect and characterize dysplastic flat lesions, which often go undetected within the colon using conventional white light endoscopy. In this study, we evaluated the ability of our surface enhanced Raman scattering (SERS) gold nanoparticles to effectively target fresh human colon cancer tissue after being covalently conjugated with a heptapeptide (VRPMLQ) sequence previously shown by our group to bind to dysplastic colonocytes in humans. Fresh human colon tissue samples, both malignant and normal adjacent tissue (NAT), were provided to us through our hospital's tissue bank. Tissue sets (malignant and NAT) from each patient (n=4) were analyzed independently. Each of the malignant and NAT samples were cut into two pieces where one was exposed for 10 min to SERS nanoparticles (0.05 nM) conjugated with the tu-

Binding efficiency of (+) heptapeptide SERS nanoparticles on tumor vs. normal human colon tissue. A) Schematic of SERS nanoparticles conjugated with tumor targeting heptapeptide. B) Digital photo of malignant tumor tissue and normal adjacent tissue. Each tissue was exposed to (+) heptapeptide SERS nanoparticles for 10 min. c) Raman image of the tissues using our Raman mapping system. D) Overlay of Raman intensity map over digital photo of fresh tissue samples. The Mighty Mouse: Ubiquitous Expression of a Tri-Fusion (Bioluminescence, Fluorescence, PET) Reporter Gene in a Transgenic Mouse Model

X Yan¹, P Ray¹, R Tong¹, A Sathirachinda¹, SS Gambhir^{1,2}
Departments of ¹Radiology, MIPS, ²Bio-X Program, Stanford University, CA.

Reporter genes are extremely useful in following the gene expression and cellular behavior in development and disease studies in mice. We have created a transgenic mouse that expresses the tri-fusion reporter gene with pcAGGS-fluc2-tdTomato-ttk vector which is driven by the chicken β -actin promoter carrying an improved bioluminescent (fluc2), an improved red fluorescent protein (tdTomato) and a truncated herpes simplex virus type 1 sr39 thymidine kinase (ttk) reporter genes. This allows one to image any cell from the donor mouse using bioluminescent, fluorescent, and PET imaging (with [18F]FHBG) techniques. Mice (N=15) with different expression levels of the tri-fusion reporter were scanned, and multimodality imaging results show that the expression level of all three genes are correlated with each other (Figure 1). In vitro luciferase assay, fluorescent assay and TK assay were performed with cell lysates from the tail of those mice, the signal levels of fluc2 (8364-5,212,160 RLU/ μ g), tdTomato (0.2-20.5 FI/ μ g) and ttk (2055.6-281,836.5 dpm) are correlated to each other ($R^2=0.99$), and the results from in vitro experiments are correlated to those from in vivo imaging. Organs

from transgenic mice with high expression level of reporter gene were harvested and tested using in vitro assays. Muscle, heart, tail, pancreas and bladder have statistically higher expression ($P < 0.05$) of reporter gene than other tissues, while the liver and intestine have less expression. To date, the signals from strong positive mice persist for 4 generations, and no developmental abnormalities/toxicity has been observed. To monitor MSC (mesenchymal stem cell) survival, FVB mice acute myocardial infarction were induced by coronary ligation with subsequent intramyocardial injection of MSC (mesenchymal stem cell) isolated from the bone marrow of the transgenic mice. Bioluminescence imaging results showed MSC signal decreased and became undetectable after 9 days. This mighty mouse will serve as an important tool in multiple fields such as stem cells and transplant biology.

Molecular Imaging

MR Imaging of Lumbar Spine using 3D FSE Cube and OsiriX: Initial Experience

EA Davalos, BH Do, GE Gold, S Biswal

PURPOSE : A novel isotropic MRI sequence, 3D Fast Spin-Echo (FSE) Cube, has the potential to complement or perhaps even replace current conventional imaging sequences. We compared 3D-FSE-Cube to conventional 2D sequences for the investigation of the lumbar spine.

METHOD AND MATERIALS: IRB approval was attained. Twenty-two patients (13 men, 9 women; ages 27-81 yrs) were referred for low back or lower extremity pain. All patients were imaged on a 3.0-T MR unit). 3D FSE Cube protocol consists of coronal FSE T2-weighted pulse sequence with fat-saturation (TE/TR (3,000/35); 26-cm FOV; 288 x 256; bandwidth, 195; 90° flip angle. Post-processing techniques, including MIP and multiplanar reformation, were used to generate images of the lumbar spine with Osirix software. The images from both conventional and 3D FSE Cube scans were reviewed side by side for each case by two radiologists with experience in musculoskeletal MRI. Radiologists were blinded to each other. Each reviewer classified the relative degree of diagnostic confidence for the 3D FSE Cube images

compared to the conventional images using a 3-point scale (were more confident, less confident, or equally confident) in their ability to assess for several spinal pathologies.

RESULTS: Images were reviewed for spinal canal stenosis, neural foraminal narrowing, pars defect, bone marrow edema, facet fluid, focal bone lesions, cord signal abnormality and annular fissure. The diagnostic confidence was higher or equal for the 3D FSE Cube images in the evaluation of spinal canal stenosis, lateral recess stenosis, pars defect, and facet fluid (22/22, 100% of patients). The diagnostic confidence was lower for the 3D FSE Cube images in the evaluation of neural foraminal narrowing, bone marrow edema, focal bone lesions, cord signal abnormality and annular fissure (22/22, 100% of patients).

CONCLUSION: 3D FSE Cube sequence improves the detection of pars defect, lateral recess stenosis and central canal stenosis. With further optimization of this sequence, it could potentially eliminate the need for 2D acquisitions in multiple planes, thus decreasing image time.

CLINICAL RELEVANCE/APPLICATION: Our preliminary experience has shown that the 3D FSE Cube sequence could improve diagnosis of certain spinal pathologies.

Imaging Pain Generators Using PET-labeled Sodium Channel Toxin Derivatives and PET-MRI

D Behera, A Hoehne, B Shen, W Parsons, D Yeomans, J Du Bois, F Chin, S Biswal

Purpose: Voltage gated sodium channel (NaV) play a critical role in the formation of action potentials. Its expression is enhanced in neuronal and inflamed tissues that promote nociceptive activity, and NaV can be targeted using a radiolabeled saxitoxin derivative ([18F]STX), which has nanomolar affinity for NaV. Using microPET-MRI we determined the localization of [18F]STX in a neuropathic pain model.

Materials and Methods: Conjugation of [18F]SFB with 6-aminohexylcarbamoyl-saxitoxin (6-AHC-STX) provided [18F]STX. Animal experiments were approved by Stanford IACUC. Spared-Nerve Injury (SNI) models (neuropathic pain model) were created in adult male Sprague-Dawley rats (n=5). The right hind limb was used as control. The rats were allowed 4 weeks to heal and develop pain. Presence of pain was ascertained by testing for allodynia using von-Frey’s filaments. Each rat was given approximately 500 µCi of [18F]STX intravenously followed by an immediate dynamic scan of the thighs for 20 minutes using a microPET, followed by T1-weighted fast spin echo images obtained using a 7T small-animal MRI. The cold [19F]STX analog (0.08 mg/kg) was co-administered

for blocking studies. PET-MRI fusion was performed using Amide image analysis software. For image analysis, ROIs were placed on 5 mm segments of sciatic nerves, proximal to the level of injury, in both hindlimbs of each rat using MR images and counts were recorded from the fused PET images. The maximum signal in each nerve was normalized to the average signal from adjacent muscle.

Results: Measured IC50 of [19F]STX against NaV was 10.6±0.8 nM in PC12 cells. Presence of allodynia in the operated limb was confirmed using von-Frey’s filaments (p<0.003). Increased [18F]STX uptake was seen in the SNI nerve compared to control side between 10-15 minutes after injection (normalized PET signal on SNI side is 2.25 ± 0.43 while it is 1.6 ± 0.19 on

control side; p<0.05), but not in the blocked studies (SNI side 1.82 ± 0.07; control side 2.09 ± 0.003; p=0.17).

Conclusion: Rats with neuropathic pain show increased [18F]STX uptake in the affected nerve. PET-MRI can be effectively used to study [18F]STX uptake in nerves.

Clinical Relevance: Combining the high sensitivity of PET with the excellent tissue contrast of MRI to locate nerves, PET-MRI with [18F]STX can quantify neural NaV channel density and potentially identify chronic pain generators.

Optical Imaging with a HER2-targeted Affibody can monitor Hsp90 treatment response in a xenograft mouse model

SM Van de Ven^{1,3}, SG Elias^{5,3}, CT Chan^{2,3}, Z Miao^{2,3}, Z Cheng^{2,3}, A De^{2,3}, SS Gambhir^{3,4}

¹Radiology, ⁵Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Netherlands; Departments of ²Radiology, ³MIPS, ⁴Bioengineering, Stanford University, CA

Aim: The goal of this study was to determine if fluorescence imaging with a HER2-targeted affibody can be used for non-invasive and repetitive imaging of HER2 expression and monitoring of the Hsp90 treatment effect on HER2 expression in human breast cancer xenografts in mouse models. **Methods:** MCF7 parental cells and two clones (A and B) transfected with HER2 were used for characterization by flow cytometry and western blotting, and to establish human breast cancer xenografts in nude mice. Anti-HER2 affibody (ZHER2:342) was labeled with AlexaFluor680 for optical imaging studies. Mice received either 120 mg/kg of the Hsp90 inhibitor 17-DMAG in 4 doses at 12 hour intervals i.p. (n=10), or PBS as a carrier control in a similar dosing scheme (n=5). Time-resolved fluorescence optical images were obtained at 4 different days: pre-treatment at day -1, and post-treatment at day 3, 6, and 9. On each imaging day optical images were acquired pre- and 5 hours post-injection of 500 pmol of Affibody-AlexaFluor680

in a volume of 150 µl via tail vein. Mice were sacrificed at day 9 and tumors were excised to correlate in vivo optical imaging signal with ex vivo HER2 levels by western blot. **Results:** Cell culture studies showed that HER2 expression was dependent on 17-DMAG dose. In vivo optical imaging signal was reduced by 21% in Clone B tumors (p=0.016) and by 13% in MCF7 parental tumors (p=0.063) at 3 days after 17-DMAG treatment; optical imaging signal recovered in both tumor types at day 6-9 after 17-DMAG treatment. In the carrier group no significant signal reduction was observed. Pearson correlation coefficient of in vivo optical imaging signal with ex vivo HER2 levels ranged from 0.74 to 0.89. **Conclusion:** Optical imaging with an affibody can be used to non-invasively monitor changes in HER2 expression in vivo in response to treatment with an Hsp90 inhibitor. This work supports the use of pre-clinical models to monitor drug efficacy in a low-cost high-throughput fashion with optical imaging.

Intravital Microscopy Reveals Surprising Differential Extravasation of Quantum Dots and Nanotubes Across Multiple Tumor Models in Living Subjects

BR Smith¹, S Tabakman², H Dai², SS Gambhir¹

Departments of ¹Radiology, MIPS, ²Chemistry, Stanford University, CA

Nanoparticles (nps) comprising various materials, shapes, and sizes are becoming ubiquitous within molecular imaging, particularly for cancer diagnosis/treatment. Because nps are typically introduced via intravenous injection and expected to localize in tumor, a deeper understanding of how and why these nps extravasate from tumor neovasculature into interstitium is critical. It is essential to the field to characterize shape- and size-dependent np behavior across multiple tumor varieties in order to provide researchers with the ability to design the appropriate np for its purpose. This will also help optimize np formulations and decrease the time for clinical translation. We probed the extravasational behavior of two np types with three different tumor types using intravital microscopy (IVM) in 30 living mice. We used nude mice with an ear tumor model. We employed near-infrared (800nm) emitting quantum dots (qdots) (~20 nm diameter) and single-walled carbon nanotubes (SWNTs, 2 nm X 200 nm) conjugated to Cy5.5. Three different tumor cell lines were employed, all transduced with EGFP for

visualization: SKOV3, LS174T, and U87MG cells. Long-circulating dye was injected to visualize the vasculature. No extravasation occurred in SKOV-3 with either np. In U87MG tumors, SWNTs extravasated rapidly (35.1% average fluorescence increase in interstitium from 2 to 30 minutes post-injection) while qdots extravasated minimally (12.7% increase from 2 minutes to 1.5 hours). However, intriguingly in LS174T tumors the opposite occurred: qdots extravasated rapidly (294% increase from 2 minutes to 1.5 hours), while SWNTs extravasated minimally. This role reversal reveals unanticipated complexity in np extravasational behavior and we quantified it using a region of interest analysis to better understand the underlying mechanisms. We thus directly visualized np extravasation from tumor blood vessels and demonstrated surprising np- and tumor-dependent differences, which will aid in the design of nps for optimal tumor uptake.

How Do Nanoparticles Target Cancer? Real-time Microscopic Imaging with Carbon Nanotubes in Mouse Tumor Models

BR Smith¹, C Zavaleta¹, Z Liu², J Ramunas³, J Rosenberg¹, R Tong⁴, H Dai², SS Gambhir^{1,4}

While nanoparticles have become invaluable in the molecular imaging toolkit, little is known about the mechanisms by which they target diseased tissues. Single-walled carbon nanotubes (SWNTs) were previously demonstrated to display among the highest tumor uptake across nanoparticle constructs (12-15% ID/g). We thus carefully examined the modes of uptake by directly observing SWNTs entering tumor vasculature, specifically binding luminal targets, extravasating from vessels, and binding to tumor cells over time. To understand the fundamental mechanisms underlying SWNT tumor uptake, we confirmed and correlated our intravital microscopy (IVM)

Using an algorithm, we binarized our tumor cell image data from living mice (left), obtaining an image showing cell (green) and bound SWNTs (yellow). On the right, a graph shows the behavior of SWNTs depending on if the ligand is specific (RGD) or non-specific (RAD). Over the first week, SWNT association is similar between the two, but afterward RGD_SWNTs tend to remain bound over 3 weeks post-injection.

results with macroscopic Raman imaging, which quantifies SWNTs’ intrinsic Raman signal. We used RGD peptide-bound SWNTs and controls to study the kinetics and routes of SWNT uptake and the ability of integrin targeting to enhance SWNT uptake and retention. We prepared targeted SWNTs by conjugating RGD (targeting αvβ3-integrins expressed on tumor neovasculature and some tumor cells, ~60/SWNT) and Cy5.5 dye (22/SWNT). Dorsal window chambers were surgically implanted into mice and EGFP-U87MG (expressing αvβ3-integrins) or EGFP-SKOV3 tumor cells were inoculated. 25 mice (U87MG, SKOV-3, no

tumor) were imaged with RGD-SWNTs (~60 pmol) and RAD and no peptide controls. Mice were imaged during tail-vein injection and frequently over the following two months with Raman and IVM. Unlike controls, RGD-SWNTs were observed to bind tumor blood vessels. Within hours, all SWNT conjugates extravasated in U87MG tumor beds, but not SKOV-3 as quantified using 10-50 fields-of-view per mouse per time point. RGD-SWNTs were observed associated with tumor cells in U87MG tumors significantly more than RAD-SWNT controls (P<0.0001). Furthermore, RGD-SWNTs differentially bound tumor cells over time compared with controls (P<0.007) and they persisted in tumor for more than a month. Control SWNTs cleared within ~1 week. In summary, IVM allowed detailed exploration of the mechanisms of SWNT uptake in tumor. This work offers unprecedented understanding of the mechanisms/temporal framework of nanoparticle dynamics in tumors, which should translate into superior properties for pre-clinical and clinical utility.

Barnes P.	Imaging of fetal and neonatal brain abnormalities. Birth Injury Group. American Association of Justice; July 11, 2010; Vancouver, BC Canada.
Barnes P.	Child Abuse and the Mimics. Update on Issues & Controversies in the Era of Evidence-based Medicine. Imaging of Pediatric CNS Malformations. Pediatric Head & Neck Imaging I & II. Pediatric Spine Imaging. Department of Radiology at University of British Columbia's Children's Hospital; October 13, 2010; Vancouver, BC Canada.
Beaulieu CF.	Optimization of MDCT for MSK Applications. MRI of the Brachial Plexus - Have no Fear. MRI of the Knee - Beyond the Menisci and Ligaments. Essentials of MSK Procedures. 19th Annual Diagnostic Imaging Update; March 2011; Kauai, HI.
Beaulieu CF.	Technical Aspects of MRI of the Knee. 20th Annual Current Concepts in MRI; October 27, 2010; Monterey, CA.
Biswal S.	New Developments in Imaging for Musculoskeletal Pain. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.
Biswal S.	Sodium Ion Channel-Selective Toxins As Tools For Imaging Pain Generators. Bio-X Interdisciplinary Initiatives Symposium; August 25, 2010; Stanford, CA.
Blankenberg F.	Oxidative Stress in Apoptosis and Mitochondrial Related Disease. 2010 ALS User's Meeting Workshop Infrared Spectromicroscopy: The Berkeley Synchrotron Infrared Structural Biology (BSISB) Program; October 14, 2010; Lawrence Berkeley National Laboratories, CA.
Blankenberg F.	In Vivo Imaging of Cell Death. 7th Annual Training Course on Concepts and Methods in Programmed Cell Death & 18th Euroconference on Apoptosis / ECDO; September 2010; Ghent, Belgium.
Blankenberg F.	Oncologic Imaging in the Era of Molecular Medicine. Imaging of Apoptosis. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.

Other Scientific Meeting Presentations

Other Presentations 2010

Blankenberg F.	Apoptosis – The Target and Challenge. Society of Nuclear Medicine; June 5, 2010; Salt Lake City, UT.
Butts-Pauly K.	Image Guidance of Focused Ultrasound. 52nd Annual Meeting of the American Association of Physicists in Medicine (AAPM); July 2010; Philadelphia, PA.
Chan F.	Imaging Heart Valves in Children: An Open and Shut Case. Imaging Airways in Children: An Inside and Outside Look. Pediatric Chest CT and Radiation Dose – Cost/Benefit. 12th Annual International Symposium on Multidetector-Row CT; May 18-21, 2010; San Francisco, CA.
Chan F.	Normal Cardiac Anatomy for Imaging. How Do I Assess MAPCAs for My Surgeons? 8th SPR Symposium on Pediatric Cardiac MR / 6th Advanced Pediatric Cardiovascular Imaging Course; January 2011; Stanford, CA.
Chan F.	Practical Pediatric Vascular Imaging: MR Imaging. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.
Cheng Z.	18F-labeled Benzamides for Preclinical PET Imaging of Melanoma Metastases. 3rd Annual Scientific Retreat of the Melanoma Research Alliance; February 17, 2011; Washington, DC.
Cheng Z.	Exploring Chemical Space for Development of Novel Molecular Probes for Cancer Imaging. Howard University; February 18, 2011; Washington, DC.
Cheng Z.	Nanoprobes for Cancer Molecular Imaging. Huazhong University of Science and Technology Union Hospital; September 18, 2010; Wuhan, China.
Cheng Z.	Novel Small Proteins for Molecular Probes Discovery. National Institute of Biomedical Imaging and Bioengineering (NIBIB)/National Institutes of Health (NIH); February 18, 2011; Washington, DC.
Cheng Z.	Optical Imaging of Cancer using Bionanotechnology. University of Science and Technology of China; September 24, 2010; Hefei, China.
Daldrup-Link H.	The Future of Breast Cancer Imaging. Breast Cancer Oncology Retreat; Jan 28, 2011; UC San Francisco, CA.
Daldrup-Link H.	Imaging of Pediatric Abdominal Tumors. Children’s Hospital of Eastern Ontario Grand Rounds; February 7, 2010; Ottawa, Canada.
Daldrup-Link H.	Cell Tracking with MR Imaging and Optical Imaging. Retreat of the Institute for Stem Cell Biology and Regenerative Medicine; January 24, 2011; Stanford, CA.
Daldrup-Link H.	Pediatric GU Imaging. UCSF Radiology Resident Review Course; March 2, 2010; San Francisco, CA.
Daniel BL.	MRI of the Breast. MRI of the Prostate. Body MR: Upcoming Techniques and Applications. Body MR Cases Workshop. 20th Annual Current Concepts in MRI; October 27, 2010; Monterey, CA.
Daniel BL.	Enhancing Foci Should Be Ignored. MRI of Silicone Breast Augmentation. Breast MRI "Jeopardy" Game - Test Your Wits at Breast MRI Interpretation. To Cut or to Core...When to do Different Kinds of MRI-Guided Interventions. 9th Annual Symposium on Advances in Breast MRI; October 14, 2010; Las Vegas, NV.
Daniel BL.	Breast MRI update: Current Status and Future Directions. Stanford Medicine Imaging Center Forum; September 30, 2010; Palo Alto, CA.
Do H.	Advances in Endovascular Treatment of Stroke. Endovascular Therapy of Intracranial Aneurysms. Spinal Augmentation Procedures: Clinical Innovations and Trials Update. 18th Annual Summer Diagnostic Imaging Update; July 13-16, 2010; Vancouver, BC Canada.
Do H.	State-of-the-Art Vertebral Augmentation. 40th Annual Scientific Meeting of the Western Angiographic and Interventional Society; September 11-15, 2010; Lanai, HI.
Fahrig R.	Cardiac CT Fluoroscopy – A Convergent Technology. 6th Advanced Pediatric Cardiovascular Imaging Course; January 21-23, 2011; Stanford, CA.
Fahrig R.	Expanding Clinical Applications for DynaCT: Challenges and Solutions. COBRA (Community of Bay Area Radionuclide Imagers); March 1, 2011; Stanford, CA.

Other Scientific Meeting Presentations

Other Presentations 2010

Fahrig R.	CT Imaging Technology: Advances for Mummy Scanning. Phoebe A. Hearst Museum of Anthropology; February 23, 2011; Berkeley, CA.
Fischbein N.	Imaging Protocols and Normal Imaging Anatomy. Imaging of the Visual Pathways. Orbital Disease: A Case-Based Discussion. 2010 Bay Area Ophthalmology Course; 2010; Stanford, CA.
Fischbein N.	Advances in Spinal MR Imaging. Imaging of Central Skull Base Tumors. 20th Annual Current Concepts in MRI; October 27, 2010; Monterey, CA.
Fischbein N.	Central Skull Base Neoplasms: Imaging Spectrum. 44th Annual Meeting of the American Society of Head and Neck Radiology; October 6-10, 2010; Houston, TX.
Fischbein N.	Imaging of Nasopharyngeal and Central Skull Base Malignancy. 48th Annual Meeting of the American Society of Neuroradiology; May 15-20, 2010; Boston, MA.
Fischbein N.	Central Nervous System Imaging in the Neuro-Intensive Care Unit. 8th Annual Meeting of the Neurocritical Care Society; September 15-18, 2010; San Francisco, CA.
Fleischmann D.	Acute Aortic Syndrome: Part 1: Aortic Dissection. Acute Aortic Syndrome, Part 2: Intramural Hematoma (IMH) and Penetrating Atherosclerotic Ulcer (PAU). Pre- and Post-operative Imaging of the Aortic Root. CT Technology Update. 18th Annual Summer Diagnostic Imaging Update; July 13-16, 2010; Whistler, BC, Canada.
Fleischmann D.	Scanning and Radiation Dose Parameters in CT. Contrast Medium Induced Nephrotoxicity (CIN) Precautions and policies in patients with decreased renal function. Physiologic Basis of Contrast Medium Injection Strategies for Vascular, Neuro, and Abdominal CT. 2D and 3D Abdominal Vascular Anatomy and Pathology. 4th Stanford Computed Tomography Workshop; Nov 18, 2010; Stanford, CA.
Fleischmann D.	The ABCs of Aortic Dissection. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.
Fleischmann D.	Radiation Dose 101. The Physiologic Basis of Contrast Medium Enhancement. 3D Minisymposium: Live 3D and 4D Rendering of the Aortic Root. Lower Extremity CTA and CTV. Diagnostic Imaging Update at Bachelor Gulch; Jan 3-7, 2011; Beaver Creek, CO.
Fleischmann D.	3D and 4D Imaging of the Aortic Root. Aortic Dissection and its Complications. Society of Computed Body Tomography and MR Summer Practicum; August 8-11, 2010; Grand Teton National Park, WY.
Gambhir SS.	New Approaches for Imaging Dementia with PET. Alternatives to FDG PET-CT for Oncology. Earlier Detection of Cancer. Recent Advances in Cardiac SPECT. 19th Annual Diagnostic Imaging Update; March 2011; Kauai, HI.
Gambhir SS.	Integrating Biomarkers and Imaging. 23rd International Conference on Screening for Lung Cancer (IELCAP); October 2010; New York, NY.
Gambhir SS.	Future of Radiological Imaging in the Context of Diagnostic Medicine. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.
Gambhir SS.	Emerging Strategies for the Merger of In Vitro and In Vivo Diagnostics. NCI Think Tank Mini Workshop Board of Scientific Advisors; February 2011; Bethesda, MD.
Gambhir SS.	Novel Strategies for Early Cancer Detection. Stand Up To Cancer Dream Team Summit Meeting; January 2011; Miami, FL.
Glover G.	Dynamics of Restless State Networks. Resting State Brain Connectivity Conference; September 16-19, 2010; Milwaukee, WI.
Gold GE.	MRI of the Elbow. MRI of the Ankle. MRI of the Shoulder. MRI of the Knee. MSK MRI Technical Considerations. 15th Annual Snowmass Clinical MRI: New Essentials - What You Need to Know; February 17, 2011; Snowmass, CO.
Gold GE.	Biochemical MR Imaging: Does it have a Future in Routine Clinical Practice. 37th Annual International Skeletal Society Musculoskeletal Imaging Update; September 29, 2010; Athens, Greece.
Gold GE.	Advanced MRI of Articular Cartilage and Osteoarthritis. Cornell University Grand Rounds; March 15, 2011; NY, NY.

Other Scientific Meeting Presentations

Other Presentations 2010

Gold GE.	Advanced MRI of Articular Cartilage and Osteoarthritis. Hospital for Special Surgery Grand Rounds; March 16, 2011; New York, NY.
Gold GE.	Advanced MSK Protocols at 3.0T. MRI of the Wrist – TFCC and Ligaments. SCBT/MR Summer Practicum; August 8, 2010; Moran, WY.
Hargreaves B.	Gradient Echo Imaging – Physics for Clinicians. Guess that Artifact. 18th Meeting of the International Society for Magnetic Resonance in Medicine; May 4, 2010; Stockholm, Sweden.
Hargreaves B.	Artifacts in MRI. Body MRI Concepts. Sequences and Contrast. Gradient Echo Family Sequences. What is MRI? 20th Annual Current Concepts in MRI; October 27, 2010; Monterey, CA.
Hargreaves B.	MRI of the Hip. 4th Conference on Quantitative Measures of Osteoarthritis; June 5, 2010; Vancouver, BC Canada.
Hargreaves B.	Physics of Breast MRI at 3T. What’s My Artifact? Advanced Techniques for Breast MRI. Top 5 Technical Advances that will Affect your Breast MRI Practice. 9th Annual Symposium on Advances in Breast MRI; October 14, 2010; Las Vegas, NV.
Hargreaves B.	MRI of Articular Cartilage: Human Studies. Orthopaedic Research Society Annual Meeting; January 14, 2011; Long Beach, CA.
Hofmann LV.	Venous Thromboembolic Disease II: Chronic Venous Occlusions. Ground Control to Major Tom: When Systems in the IR Suite Break Down. 36th Annual Scientific Meeting of the Society of Interventional Radiology; March 28-31, 2011; Chicago, IL.
Hofmann LV.	Endovascular Treatment of Acute and Chronic DVT. Oakland Children’s Hospital Grand Rounds; September 15, 2010; Oakland, CA.
Hofmann LV.	A New Chronic Venous Disease Initiative. Venous Disease Coalition Conference; September 20, 2010; Washington, DC.
Hovsepian D.	Interventional Radiology in the U.S.: Uterine Fibroid Embolization. Arterial Embolization for Pelvic Trauma. 90th Anniversary Symposium of Yerevan State Medical University; October 2010; Yerevan, Armenia.
Hovsepian D.	Fallopian Tube Recanalization. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.
Hovsepian D.	Uterine Fibroid Embolization for Selected Patients. Association for Radiologic & Imaging Nursing (ARIN); October 23, 2010; Redwood City, CA.
Hovsepian D.	Introduction to Uterine Fibroid Embolization. Evening Seminar for Patient Education; May 2010; Stanford, CA.
Hwang, G	Tips and Tricks for RF Ablation: Liver. Management of Renal Tumors – Transarterial and Percutaneous: The Whole Gamut. Stereotactic Radiotherapy vs. Percutaneous Ablation Techniques: Results in Lung and Liver Tumors. Fiducial Implantation for Stereotactic Radiotherapy: How I Do It. 18th Annual Summer Diagnostic Imaging Update; July 13-16, 2010; Whistler, Canada.
Hwang, G	How to Handle Complications. Glycemic Control in the IR Suite. Liquid Embolics. 36th Annual Scientific Meeting of the Society of Interventional Radiology; March 28-31, 2011; Chicago, IL.
Iagaru A.	Imaging Angiogenesis: What can Different Modalities do? PET/CT in Angiogenesis Imaging. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.
Iagaru A.	Introduction to PET/CT. Hospital Mae de Deus Symposium; April 26, 2010; Porto Alegre, Brazil.
Iagaru A.	Lymphomas: What can Nuclear Medicine do for you? Medical Oncology Grand Rounds; November 16, 2010; Stanford, CA.
Iagaru A.	Updates on PET/CT and Thyroid Cancer. Nuclear Medicine Grand Rounds; April 6, 2010; Stanford, CA.
Ikeda DM.	Benign MRI Findings. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.

Other Scientific Meeting Presentations

Other Presentations 2010

Ikeda DM.	ACR BIRADS MRI Lexicon 2010 Update. Should Enhancing Foci be Ignored? Breast MRI in Neoadjuvant Chemotherapy and Partial Breast Irradiation. Correlating Digital Mammography, Sonography, and MRI. 9th Annual Symposium on Advances in Breast MRI; October 14, 2010; Las Vegas, NV.
Ikeda DM.	MRI Interpretation. Correlating Mammograms/US/MRI. False Negative Breast Imaging. Lesions for Biopsy. Breast 2011; March 26-27, 2011; Sydney, Australia.
Ikeda DM.	A Practical Approach to Image Interpretation. Breast MR with Guided Biopsy; February 7, 2011; Reston, VA.
Ikeda DM.	Correlating Mammography, Ultrasound and MRI. False Negative Mammo, Ultrasound, and MRI. MRI Indications. New Developments in Breast Imaging. Update in Advanced Breast Imaging; September 3-4, 2010; Bruges, Belgium.
Kamaya A.	Thyroid Nodule Evaluation and the Post Thyroidectomy Neck. HCC Imaging: What every Radiologist should know. Pregnancy and Postpartum Related Complications. Acute Gynecologic Emergency Imaging. 19th Annual Diagnostic Imaging Update; March 2011; Kauai, HI.
Komakula S.	Case Presentation: Intradural Intramedullary Lesions. 2nd Intensive Interactive Brain and Spine Imaging Conference; March 28, 2011; Salt Lake City, UT.
Kuo W.	Catheter-Directed Therapy for Acute PE. 36th Annual Scientific Meeting of the Society of Interventional Radiology; March 28-31, 2011; Chicago, IL.
Kuo W.	An Update on Retrievable IVC Filters. Complex Filter Retrieval: Advanced Techniques. Mission Impossible: Managing Filter Disasters. Endovascular Therapy for Massive PE: The Final Frontier. 4th Annual Meeting of the Latest Advances in Interventional Techniques (LAVA); July 2010; Maui, HI.
Kuo W.	Endovascular Therapy for Acute PE. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.
Levin CS.	Strategies to Advance Time-of-Flight Positron Emission Tomography (ToF-PET): Study of Detector, Image Reconstruction and System Attributes for Advancing Sub-nanosecond Timing. New Technologies for Combining PET and MRI without Mutual Interference. 2010 Korean Society of Medical Physics; September 16-17, 2010; Seoul, South Korea.
Levin CS.	Instrumentation and Algorithms for 1 Millimeter Resolution Clinical PET. 2010 Stanford-Catholic University of Korea Joint Symposium; September 7, 2010; Seoul, South Korea.
Levin CS.	Exploiting Coherent Light in Positron Emission Tomography. Beckman Laser Institute's Laser Microbeam and Medical Program Seminar Series; November 16, 2010; UC Irvine, CA.
Levin CS.	Molecular Imaging Instrumentation Research at Stanford. Central Research Laboratory of Hamamatsu Photonics; September 13, 2010; Hamamatsu City, Japan.
Levin CS.	Technologies for Combining PET and MRI without Mutual Interference. Samsung Advanced Institute of Technology (SAIT); September 15, 2010; Gyeonggi-do, South Korea.
Lin M.	MDCT of Cardiac Valve Replacements. Preoperative Imaging of Pectus Excavatum. Volumetric Assessment of Pulmonary Nodules on CT. 12th Annual International Symposium on Multidetector-Row CT; May 18-21, 2010; San Francisco, CA.
Lipson JA.	Targeted Ultrasound after Breast MRI. Anatomy, Physiology, & Pathology of the Breast. 9th Annual Symposium on Advances in Breast MRI; October 14, 2010; Las Vegas, NV.
Lipson JA.	Breast Imaging in Breast Cancer Diagnosis. Cancer Education Seminar Series; October 5, 2010; Stanford, CA.
Louie J.	Chronic Venous Occlusion. 36th Annual Scientific Meeting of the Society of Interventional Radiology; March 28-31, 2011; Chicago, IL.
Lutz A.	Early Detection of Ovarian Cancer Using Targeted Microbubble-Enhanced Ultrasound. 4th Comprehensive Cancer Research Training Program (CCRTP); September 2010; Stanford, CA.
Lutz A.	Novel Diagnostic Tools in Ovarian Cancer Early Detection. Ovarian Cancer Action/ Helene Harris Memorial Trust Meeting; January 2011; Fort Lauderdale, FL.

Other Scientific Meeting Presentations

Other Presentations 2010

Marks M.	Preliminary Analysis of Endovascular Treatment Results for DEFUSE 2 Trial. DEFUSE Investigators Meeting; October 2010; Palo Alto, CA.
Marks M.	Endovascular Treatment of Ischemic Stroke. Stanford University Hospital; September 2010; Stanford, CA.
Marks M.	Intracranial Stenting: Unique Requirements, Novel Technologies, and Present Status. Transcatheter Cardiovascular Therapeutics; September 2010; Washington, DC.
Moseley M.	Debate: Should the Diffusion-Perfusion Study Group be Split? 18th Meeting of the International Society for Magnetic Resonance in Medicine; May 4, 2010; Stockholm, Sweden.
Moseley M.	MR Basic Concepts. MR Advanced Topics. American Society Neuroimaging; January 2011; San Francisco, CA.
Napel S.	Automated Image Retrieval Based on Lesion and Case Similarity. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.
Newman B.	Anomalies of the Great Arteries. Airway Abnormalities Associated with Congenital Heart Disease. 38th Annual Meeting of the North American Society for Cardiovascular Imaging; October 3-5, 2010; Seattle, WA.
Newman B.	Disorders of the Large Airways in the Pediatric Population. 96th Scientific Assembly and Annual Meeting of the RSNA; November 28 - December 3, 2010; Chicago, IL.
Newman B.	Radiation Dose Reduction in Pediatric Cardiac CT. Advanced Pediatric Cardiac Imaging Symposium; January 18-23, 2011; Stanford, CA.
Newman B.	Point Counterpoint – Dose Related Issues in Cardiac CT Imaging. Ultrasound Body Applications in Children. ALARA CT; March 5-6, 2011; Dallas, TX.
Newman B.	Congenital Intra and Extrahepatic Portosystemic Shunts. CT of Congenital Lung Malformations in Children. CT of the Thymus in Children - Normal and Abnormal. 12th Annual International Symposium on Multidetector-Row CT; May 18-21, 2010; San Francisco, CA.
Nino-Murcia M.	Abdomen and Pelvis Cases. CT Review for the Nuclear Medicine Physician - Department of Veterans Affairs Employee Education System and Nuclear Medicine Service Postgraduate Course; August 3, 2010; Palo Alto, CA.
Paik D.	MicroCT Image Analysis. Caliper Life Sciences; May 2010.
Paulmurugan R.	Novel Imaging Assay Technologies to Monitor Fundamental Cellular Events in Living Subjects. 8th World Congress on Trauma, Shock, Inflammation and Sepsis; March 9-13, 2011; Munich, Germany.
Plevritis S.	Modeling the Natural History of Lung Cancer. Canary Foundation Annual Lung Cancer Working Group Meeting; March 28, 2011; Palo Alto, CA.
Plevritis S.	Radiogenomics: Integration of Medical Images and Transcriptomic Data in Non-Small Cell Lung Cancer. National Institute of Biomedical Imaging and Bioengineering; December 17, 2010; Bethesda, MD.
Plevritis S.	Systems Biology of Cancer. Stanford Hematology and Oncology Retreat; October 28, 2010; Asilomar, CA.
Plevritis S.	Modeling the Role of Differentiation in Cancer Progression. UCSF Cancer Center Workshop on Physical and Computational Approaches in Cancer Biology; March 18, 2011; San Francisco, CA.
Poulios P.	Virtual Colonoscopy for the Radiology Nurse. Radiologic Imaging Nurses Symposium; October 23, 2010; Redwood City, CA.
Poulios P.	Virtual Colonoscopy for the Technologist. Stanford CT Technologist In-Service; April 14, 2010; Stanford, CA.
Quon A.	FDG and Physiologic Effects on Medical Devices. Roche Advisory Board Meeting; December 2010.
Quon A.	Molecular Imaging and PET/CT From the Physician's Perspective. GE Molecular Imaging University; March 2011.
Quon A.	PET/CT and Nuclear Medicine in Neuroendocrine Tumors. Stanford Caring for Carcinoid Foundation; September 2010; Stanford, CA.

Other Scientific Meeting Presentations

Other Presentations 2010

Quon A.	PET/CT and the Post-Therapy Evaluation of Head/Neck Cancers. PET/CT Head/Neck Cases. UCSF Radiation Oncology Seminar on Head/Neck Cancers; April 2010; UC San Francisco, CA.
Rao J.	Drug Development: Choosing the Right Imaging Platform for your Drug or Biologic. 2010 National Biotechnology Conference; May 19, 2010; San Francisco, CA.
Rao J.	Novel Approaches to Imaging Protease Activity In Vivo. 2010 WMIC Preconference Satellite Meeting; September 6, 2010; Seoul, South Korea.
Rao J.	Metals in Biology. 240th Fall Annual Conference of the American Chemical Society; August 22-26, 2010; Boston, MA.
Rao J.	Proprotein Processing, Trafficking & Secretion. Gordon Research Conferences at Colby-Sawyer College; July 18-23, 2010; New London, NH.
Rao J.	Building Molecules for In Vivo Imaging of Biology and Diseases. Institute for Bioscience and Biotechnology Research (IBBR); April 25, 2011; University of Maryland College Park, MD.

CBIS Seed Funding

The mission of the Center for Biomedical Imaging at Stanford (CBIS) is to facilitate the clinical, research, and educational mis- sions of Stanford within the imaging community. Major events supported by CBIS include the annual campus-wide Symposium, mini symposia, seminars, and the Seed Grant Program. New programs in 2011 include the “Q&A at the Scan Centers” program, the CBIS Report, an electronic newsletter with each issue presenting a CBIS faculty member profile. This year’s CBIS Seed Grant Recipients are listed here. For more information about the Seed Grant funded projects, please see: <http://cbis.stanford.edu/people/2011seedgrants.html>.

Collaborating Stanford Departments

We work with almost three hundred faculty, postdoctoral fellows, students, and research staff from across the University. We wish to thank you all for the friendly, productive collaborations that we enjoy all year long. Stanford departments with whom we have long-standing research projects include the following:

Aeronautics and Astronautics Anesthesia Applied Physics Biochemistry Bioengineering Biology Bio-X Cancer Biology Cancer Center Cardiothoracic Surgery Chemical Engineering Chemistry Comparative Medicine Computer Sciences Developmental Biology Electrical Engineering ENT Freeman Spogli Institute Genetics Health Research and Policy Hematology Infectious Diseases Institute for Computational & Mathematical Engineering Lucile Packard Children’s Hospital Materials Science and Engineering	Mathematics Mechanical Engineering Medical Informatics Medicine Microbiology and Immunology Molecular and Cellular Physiology Neurobiology Neurology and Neurological Sciences Neurosurgery Obstetrics & Gynecology Oncology Ophthalmology Orthopedics/Orthopedic Surgery Otolaryngology Pathology Pediatrics Pediatrics/Neonatology Physics Psychiatry and Behavioral Sciences Psychology Radiation Oncology Stanford Center for Biomedical Ethics Stroke Center Surgery Urology
